North Dakota Corn

Variety Trial Results for 2019 and Selection Guide

Joel Ransom and Darin Eisinger (NDSU Main Station); Blaine Schatz, Mike Ostlie and Tim Indergaard (Carrington Research Extension Center); Eric Eriksmoen, Joe Effertz and Austin Kraklau (North Central Research Extension Center, Minot); Kelly Cooper, Heidi Eslinger and Seth Nelson (Oakes Irrigation Research Site); Justin Jacobs and Tyler Tjelde (Nesson Valley Irrigation Site); John Rickertsen and Michael Wells (Hettinger Research Extension Center); Jerry Bergman, Gautam Pradhan, Cameron Wahlstrom and Meridith Miller (Williston Research Extension Center)

This publication reports the results of corn hybrid trials that were conducted by NDSU research and Extension personnel throughout North Dakota. The hybrids tested were entered voluntarily by the companies that market them, and the management of these trials was financed partially by the entry fee those companies paid. Links to the participating companies are summarized in Table 1. Additional information and data for a given location may be available at www.ag.ndsu.edu/varietytrials/corn and www.ag.ndsu.edu/cornhybridtesting. When selecting a hybrid, look at its performance at multiple locations and/or across years if possible.

Corn Production and Weather in 2019

In 2019, the area of corn planted in North Dakota was 3.55 million acres, up from the 3.15 million acres planted in 2018. The average yield for the state in 2019 was estimated at 142 bushels per acre, down from the 146 bushels per acre recorded in 2018.

Corn was planted later than normal due to a cool, wet spring. That, coupled with significantly fewer growing degree days (GDD) during the summer, resulted in delayed maturity. October and November were cold and wet, so most corn dried little, resulting in nearly 2 million acres still unharvested at the time of writing (Dec. 15).

Experimental Procedures

Hybrids were planted in replicated plots in each location. Plot size, number of replications and experimental design varied by location. Information regarding planting and harvesting dates and other management practices is available from the researchers implementing the research. Grain yield was adjusted to 15.5% moisture.

Data Analysis

Data were analyzed using analyses of variance (ANOVA). Least significant differences (LSDs) at the 5% and 10% levels were calculated from these analyses and are placed at the bottom of each column of data. These LSD values apply only to the numbers in the column in which they appear. If the difference (for instance, for yield) between two varieties exceeds the LSD value, it means that with 95% or 90% confidence, the higher-yielding variety has a significant yield advantage. Conversely, when the difference between the means of two varieties is less than the LSD value, this indicates these varieties have no statistical difference between them. The coefficient of variation (CV), which also is placed at the bottom of each column, is a measure of the variability for that trait within the trial.

Hybrids are ranked in descending order for yield in each table. Carefully consider grain moisture at harvest in addition to yield. Comparing the yield of hybrids with similar moisture levels allows you to compare the yield of hybrids with similar relative maturities (RMs). The RMs listed in the tables have been provided by the company marketing these hybrids. In some cases, the industry-provided estimate of RM might not correspond precisely to the moisture levels obtained in trials reported in this publication.

Special Notes for 2019

Results from the corn hybrid trial at Langdon are not reported due to a snowstorm rendering the plots unharvestable. Corn was very wet in most locations at the time of harvest. Moisture meters were used to obtain an estimate of the moisture content of the grain at harvest. Even though the meters used were calibrated for high moisture, the values recorded were higher than the normal range. Freezing temperatures also may have impacted the results from these meters; therefore, the values listed in the publication are more variable and less accurate than normal, especially for values greater than 30%, although the relative mean values are thought to still be useful in comparing hybrids.

When test weight is reported, the grain sample was oven dried before measuring. This drying process may have resulted in the samples having a slightly lower test weight than might be obtained by natural field drying, but may be similar to what is obtained from artificial drying on the farm.
