Complementary Rotation Grazing System – 1984

Dickinson Experiment Station

L. Manske and T. J. Conlon

The 1984 grazing season was the second year of the complementary rotation grazing system at the ranch headquarters of the Dickinson Experiment Station. The complementary rotation grazing system consists of a crested wheatgrass (Agropyron desertorum) pasture for spring grazing, a native range three pasture rotation with twice over on each pasture for summer grazing, and an altai wildrye (Elymus angustus) pasture for fall and early winter grazing. The trial compares animal performance and herbage production between two treatments. The east treatment will be interseeded with a pasture type alfalfa and the west treatment will not be interseeded and used as a control. The east treatment was interseeded in the spring of 1984 but the seedlings failed to become established because of the lack of precipitation in July. Pasture type alfalfas (Medicago falcata) are more difficult to establish and the seedlings are less tolerant of drought conditions than the hay type alfalfas (M. sativa). Within each treatment, the herbage data was compared between the effects of grazing and ungrazing. During the 1983 grazing season both treatments were untreated to establish baseline data.

The soils of the crested wheatgrass and altai wildrye pastures are primarily silt loams and loams. The soils of the native range pastures are primarily fine sandy loams, loams, silty clay loams, silt loams and silty clay.

The crested wheatgrass and altai wildrye pastures were treated as monoculture pastures. The crested wheatgrass pastures were seeded prior to the experiment station occupation. The altai wildrye was seeded into fallow soil in the spring of 1982 at a seeding rate of 8 pounds PLS per acre. Fifty pounds of nitrogen per acre was broadcast applied on each crested wheatgrass and altai wildrye pasture in the spring of 1984.

The native range pastures are on mixed grass prairie with four major range sites which are clayey, sandy, shallow and silty. The dominant graminoids are blue grama (Bouteloua gracilis), threadleaved sedge (Carex filifolia), western wheatgrass (Agropyron smithii) and prairie junegrass (Koeleria pyramidata).

The data that was collected from these pastures were above ground herbage production, species composition by ten pin point frame and 0.1 meter square quadrats, leaf height measurements and phenological phases of eight major graminoid species, and animal performance by weight changes.

Four samples sites were systematically selected for each of the tame grass pastures. Each of the native range pastures had a sample site on each of the four major sites. Each of the respective range site sample sites were selected for similar soil, slope, and aspect in each pasture.

The above ground herbage production was sampled by clipping the vegetation to ground level inside $\frac{1}{4}$ meter square quadrats both inside and outside enclosure cages. The herbage was separated into nine categories: cool short, warm short, cool mid, western wheatgrass, warm mid, warm tall, sedges, forbs, and shrubs. The samples were oven dried at 80°C. The average herbage production for each category and the total production for each site were determined for each clipping period.

Quantitative species composition data were collected by the ten pin point frame method (Levy and Madden 1933, Tinney, Aamodt, and Ahlgren 1937, Heady and Rader 1958, and Smith 1959). One thousand points were read for each sample site. Forb and shrub density data were collected with a 0.1 meter square quadrat. The forbs and shrubs that were rooted within the frame were counted by species in each of the 25 quadrats per sample site.

Monthly leaf height measurements and phenological development of the flower stalks were collected for nine dominant graminoid species: Agropyron desertorum, Elymus angustus, Agropyron smithii, Bouteloua gracilis, Calamovilfa longifolia, Koeleria pyramidata, Poa pratensis, Stipa comata and Carex filifolia. Twenty four plants of each species were selected at random on each sample site. All of the leaves of each plant were outstretched and measured to the nearest millimeter in sequence from the oldest to youngest. Along with the length measurements, the degree of dryness for the leaf blades were recorded. The categories of dryness used were: 0, 0.1-2, 2.1-25, 25.1-50, 50.1-75, 75.1-98 and 100 percent dry. The highest value of the category was used to record the percentage of dryness for each leaf blade.

If the flower stalks were present, the height was measured and the phenological stage of development was recorded. The categories used were: flower stalk developing, head emergence, anthesis, seeds developing and seeds being shed.

Alfalfa seedling densities per meter of row were collected on each range site of the east treatment both grazed and ungrazed in July and August.

Animal performance was determined by weight gains or losses. Cattle were weighed on and off each pasture during the scheduled rotation periods. These data were converted into mean weight gain in pounds per day per head and mean weight gain in pounds per day per acre for the calves, cows and bulls. Nineteen cow-calf pairs of commercial Hereford and Hereford X Angus were used on each treatment in 1984.

Se ve	<i>Setaria verticillata</i>	Bur pigeongrass
Se vi	<i>Setaria viridis</i>	Green pigeongrass
St co	<i>Stipa comata</i>	Needleandthread
St vi	<i>Stipa viridula</i>	Green needlegrass

Graminoids (Continued)

Ca el	Carex eleocharis	Needleleaf sedge
Ca fi	Carex filifolia	Threadleaved sedge
Ca he	Carex heliophila	Yellow sedge
El spp.	Eleocharis spp.	Spikerush

Forbs:

Ac mi	Achillea millefolium	Yarrow
Ag gl	Agoseris glauca	Prairie dandelion
Al ai	Allionia ainearis	Four O'clock
Al te	Allium textile	White wild onion
Am re	Amaranthus retroflexus	Rough pigweed
An oc	Androsace occidentalis	Fairy candelabra
An cy	Anemone cylindrica	Cottonweed
An ne	Antennaria neglecta	Pussytoes
An pa	Antennaria parvifolia	Pussytoes
Ar ho	Arabis holboellii	Slim rockcress
Ar ca	Artemisia caudata	Green sage
Ar dr	Artemisia dracunculus	Green sage
Ar fr	Artemisia frigida	Fringed sage
Ar lu	Artemisia ludoviciana	White sage
As ve	Asclepias verticillata	Whorled milkweed
As vi	Asclepias viridiflora	Green milkweed
As er	Aster ericoides	White prairie aster
As ca	Astragalus canadensis	Little rattlepod
As cr	Astragalus crassicarpus	Ground plum
Ce ar	Cerastium arvense	Prairie chickweed
Ce la	Ceratoides lanata	Winter fat
Ch al	Chenopodium album	Lamb's quarters

Forbs (Continued):

Ch vi	<i>Chrysopsis villosa</i>	Golden aster
Ci un	<i>Cirsium undulatum</i>	Prairie thistle
Co um	<i>Commandra umbellata</i>	Bastard toadflax
Co ar	<i>Convolvulus arvensis</i>	Field bindweed
Co ca	<i>Conyza canadensis</i>	Horseweed
Co vi	<i>Coryphantha vivipara</i>	Ball cactus
De pi	<i>Descurainia pinnata</i>	Tansy mustard
De so	<i>Descurainia sophia</i>	Flixweed
Ec an	<i>Echinacea angustifolia</i>	Purple coneflower
Er gl	<i>Erigeron glabellus</i>	Rough erigeron
Er spp.	<i>Erigeron spp.</i>	Daisy fleabane
Er fl	<i>Eriogonum flavum</i>	Yellow umbrella plant
Er mu	<i>Eriogonum multiceps</i>	Eriogonum
Er as	<i>Erysimum asperum</i>	Western wallflower
Eu di	<i>Euphorbia dictyosperma</i>	Spurge
Eu ge	<i>Euphorbia geyeri</i>	Geyer's spurge
Eu ma	<i>Euphorbia maculata</i>	Nodding spurge
Ga co	<i>Gaura coccinea</i>	Gaura
Gr sq	<i>Grindelia squarrosa</i>	Gumweed
Gu sa	<i>Gutierrezia sarothrae</i>	Broomweed
Ha sp	<i>Haplopappus spinulosus</i>	Spiny ironweed
He hi	<i>Hedeoma hispida</i>	Rough pennyroyal
He ri	<i>Helianthus rigidus</i>	Stiff sunflower
Hi vu	<i>Hippuris vulgaris</i>	Marestail
Hy ri	<i>Hymenoxys richardsonii</i>	Rubber plant
Ko sc	<i>Kochia scoparia</i>	Kochia
La ob	<i>Lactuca oblongifolia</i>	Blue wild lettuce
Le de	<i>Lepidium densiflorum</i>	Peppergrass
Li pu	<i>Liatis punctata</i>	Blazing star
Li ri	<i>Linum rigidum</i>	Stiffstem flax

Forbs (Continued):

Li in	<i>Lithospermum incisum</i>	Narrow-leaved puccoon
Lo am	<i>Lotus americanus</i>	Prairie bird's foot trefoil
Ly ju	<i>Lygodesmia juncea</i>	Skeleton weed
Ma ro	<i>Malva rotundifolia</i>	Small mallow
Me fa	<i>Medicago falcata</i>	Alfalfa
Me of	<i>Melilotus officinalis</i>	Yellow sweetclover
Mu di	<i>Musineon divaricatum</i>	Wild parsley
Ne pa	<i>Neslia paniculata</i>	Ball mustard
Oe se	<i>Oenothera serrulata</i>	Tooth-leaved evening primrose
Op fr	<i>Opuntia fragilis</i>	Brittle prickly pear
Or lu	<i>Orthocarpus luteus</i>	Owl clover
Ox la	<i>Oxytropis lambertii</i>	Purple loco
Pe al	<i>Penstemon albidus</i>	White beardtongue
Pe pu	<i>Petalostemon purpureum</i>	Purple prairie clover
Ph ho	<i>Phlox hoodii</i>	Moss phlox
Pl pu	<i>Plantago purshii</i>	Woolly plantain
Po al	<i>Polygala alba</i>	White milkwort
Po ar	<i>Polygonum arenastrum</i>	Common knotweed
Po co	<i>Polygonum convolvulus</i>	Wild buckwheat
Po pe	<i>Potentilla pensylvanica</i>	Potentilla
Ps ar	<i>Psoralea argophylla</i>	Silverleaf scurfpea
Ps es	<i>Psoralea esculenta</i>	Indian breadroot
Ra cy	<i>Ranunculus cymbalaria</i>	Seaside buttercup
Ra co	<i>Ratibida columnifera</i>	Long headed coneflower
Sa ka	<i>Salsola kali</i>	Russian thistle
Se pl	<i>Senecio plattensis</i>	Prairie ragwort
So mi	<i>Solidago missouriensis</i>	Early goldenrod
So ri	<i>Solidago rigida</i>	Stiff goldenrod
Sp co	<i>Sphaeralcea coccinea</i>	Scarlet globemallow

Forbs (Continued):

Ta of	Taraxacum officinale	Dandelion
Th rh	Thermopsis rhombifolia	False lupine
Tr du	Tragopogon dubius	Large goat's beard
Ve fa	Vernonia fasciculata	Ironweed
Vi am	Vicia americana	Wild vetch
Vi nu	Viola nuttallii	Nutall's violet
Xa st	Xanthium strumarium	Cocklebur

Shrubs:

Ju ho	Juniperus horizontalis	Creeping juniper
Ro ar	Rosa arkansana	Prairie wild rose
Sy oc	Symphoricarpos occidentalis	Wolfberry

Lycopods:

Se de	Selaginella densa	Club moss
-------	-------------------	-----------

Eumycota:

Li spp.	Species of lichens	Lichens
---------	--------------------	---------

Native Range Fertilization with Ammonium Nitrate and Urea – 1984

Dickinson Experiment Station

H. Goetz and L. Manske

A study that compares fertilization of native range between ammonium nitrate and urea was started at the Dickinson Experiment Station in the spring of 1982. The trial was established on 2.6 acres located on the SW $\frac{1}{4}$ SW $\frac{1}{4}$ NW $\frac{1}{4}$ sec. 16, T. 143 N., R. 96 W. at the ranch headquarters of the Dickinson Experiment Station. The 30 X 60 foot plots were arranged in a randomized block design with three replications. The alleys between the replications were 10 feet wide and the perimeter border was 40 feet wide. A barbed wire fence was constructed to exclude grazing on the plots until after all of the data for that season were collected. The soil was moreau silty clay. The range site was clayey. The fertilization treatments were 40 and 60 pounds of nitrogen per acre for ammonium nitrate and urea applied annually and biennially, and 100 pounds of nitrogen per acre for ammonium nitrate and urea applied biennially. A total of ten fertilizer treatments and two control plots with no treatment were included in each replication. The fertilizer was broadcast applied on 4 May 1982, 1983, and 1984. The data that were collected from these plots were: above ground herbage production separated into seven categories, leaf height measurements and phenological phases of five major graminoid species, quantitative species composition, soil moisture and soil nutrient content at increments to 48 inches in depth.

The above ground herbage production was sampled by clipping to ground level two $\frac{1}{4}m^2$ quadrats for each plot. The herbage was separated into seven categories, cool short, warm short, cool mid, western wheatgrass, warm mid, sedge and forbs. The samples were oven dried at 80°C. The dried samples were then weighted in grams. The average weight of each category for the two $\frac{1}{4}m^2$ quadrats was determined and the average pounds per acre of herbage production was calculated for each category by multiplying the average weight in grams by 35.68. The total average production for each plot was found by the summation of the average pounds per acre for each category. The reported figures were means of the three replications for each treatment. Five clips were made for the 1984 season. The dates for these were 30 May, 25 June, 18 July, 1 August and 15 August.

The herbage samples were ground in a Wiley mill and analyzed for nutrient content by proximate analysis at the nutrition laboratory in the animal science department at North Dakota State University under direction of Dr. Duane Erickson. The results of these analysis will be made available at a later date.

Leaf height measurements and phenological development of the flower stalks were collected for five dominant graminoid species, Carex filifolia, Bouteloua gracilis, Koeleria pyramidata, Agropyron smithii and Stipa comata. Twelve plants of each species were selected at random on each plot. All of the leaves of each plant were outstretched and measured to the nearest millimeter in sequence from the oldest to the youngest. Along with the length measurements, the degree of dryness for the leaf blades were recorded. The categories of dryness used were: 0, 0.1-2, 2.1-25, 25.1-50, 50.1-75, 75.1-98 and 100 percent dry. The highest figure of the category was used to record the percentage of dryness for each leaf blade.

If the flower stalks were present, the height was measured and the phenological stage of development was recorded. The categories used were: flower stalk developing, head emergence, anthesis, seeds developing and seeds being shed. Leaf height and phenological development data were collected in the 1984 season. The dates for these were 7-8 June, 19-20 July and 23 August.

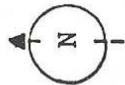

Quantitative species composition data for each plot was collected during the period of 23-30 July for the 1984 season. The herbaceous plants were sampled by the ten pin point-frame method (Levy and Madden 1933, Tinney, Aamodt, and Ahlgren 1937, Heady and Rader 1958, and Smith 1959). The point frame was a metal frame that was constructed to stand at a 60° angle with holes for ten pins spaced at 5 cm intervals. The frame was set down and the pins raised and then allowed to move down through the existing vegetation. If a pin hit the basal portion of a living plant, the species of that plant was recorded. Hits on Selaginella densa and the various species of lichens were also recorded as hits. The pins that did not make contact with living vegetation were counted as no hits. These were divided into litter (dead and decaying vegetation), soil (mineral soil not covered by litter or living vegetation) and rock (a hard mass of mineral substance large enough to obstruct plant growth, about the size of a half dollar or larger). Aerial hits were not recorded. Fifteen hundred points were read for each treatment (500 points per plot). A systematic sampling scheme was used for each plot. A permanent major transect was established two feet inside and parallel to the north boundary of each plot. Five minor transects were established perpendicular to the major transect at three foot intervals starting three feet from the east boundary of the plot. One hundred points were read on each minor transect.

Forb and shrub densities were sampled by the use of one tenth meter square quadrats. The forbs and shrubs that were rooted within the frame were counted by species in each of the 10 quadrats per plot, 30 quadrats per treatment.

Soil moisture by the gravimetric method was taken three times during the 1984 season. The dates for these were 26 June, 25 July, and 27 August. The one inch Veihmeyer soil tube was used to collect the samples. Three locations were selected as sample sites for the trial, at the north end, in the center and at the south end. Two replications were taken at each location. The samples were collected at increments of 0-6, 6-12, 12-24, 24-36 and 36-48 inches in depth. Each subsample was placed in a numbered steel can of known weight. These were weighted, then oven dried at 100°C. The dried soil cans were again weighted. The difference in weight was the weight of the soil water. Percent soil moisture was then calculated.

Soil nutrient content was collected monthly during the 1984 season. The dates for these were 26 June, 26 July and 27 August. The samples were collected using the one inch Veihmeyer soil tube. Three replications were taken from each treatment. The samples were collected at increments of 0-6, 6-12, 12-24, 24-36, and 36-48 inches in depth. Each subsample was placed in labeled soil bags and frozen. The samples were analyzed for nutrient content by the soils laboratory at North Dakota State University.

The month of May was very dry. The first precipitation occurred 33 days after the application of the fertilizer. It was suspected that a large amount of the ammonia from the fertilizer volatized in 1984.

ALFALFA INTERSEEDING TECHNIQUES TRIAL – 1984

Dickinson Experiment Station

Llewellyn Manske

The alfalfa interseeding techniques trial is separated into three separate segments. These are: alfalfa interseeding row spacing techniques trial, alfalfa interseeding furrow width techniques trial, and interseeded alfalfa variety response to grazing trial.

The personnel at the Dickinson Experiment Station built an interseeding machine during the winter of 1982-83. The plans from a machine designed and tested at South Dakota State University (Chisholms et al. 1980) were used for the construction with slight alterations. This interseeder was used to establish the alfalfa interseeding plots in 1983.

ALFALFA INTERSEEDING ROW SPACING TECHNIQUES TRIAL

This trial was designed to evaluate alfalfa interseeding into rangeland with different intervals between the rows. The intended purpose of the data will be primarily to assist in the determination of a recommended row spacing or row spacings for alfalfa interseeding into rangeland for pasture use in western North Dakota.

These plots were established on one acre located on the NE^{1/4}, NW^{1/4}, SW^{1/4} sec. 23, T. 143 N., R. 96 W. at the ranch headquarters of the Dickinson Experiment Station. The 33 x 50 foot plots were arranged in a randomized block design with three replication. The soil was vebar fine sandy loam. The range site was sandy with a few thin claypan sites. Travois alfalfa was seeded at a rate of 0.50 lbs PLS/row/acre on 21 April 1983. A four inch twisted chisel plow shovel was used as the furrow opener. The intervals between the rows were 2, 3, 4, 5, 8 and 10 feet. A control plot of no interseeding was included in each replication.

The data that were collected from these plots were: above ground herbage production separated into nine categories, alfalfa seedling counts per meter of row, species composition by point frame and forb densities by use of one tenth meter square quadrats.

The above ground herbage production was sampled by clipping the vegetation to ground level in two $\frac{1}{4}$ m² quadrats for each plot on 22 June 1984. The herbage was separated into nine categories, cool short, warm short, cool mid, western wheatgrass, warm mid, warm tall, sedge, forbs and shrubs. The samples were oven dried at 80°C. The dried samples were then weighted in grams. The average weight of each category for the two $\frac{1}{4}$ m² quadrats was determined and the average pounds per acre of herbage production was calculated for each category by multiplying the average weight in grams by 35.68. The total average production for each plot was found by the summation of the average pounds per acre for each category. The reported figures are means of the three replications for each treatment.

The alfalfa seedling counts were made by counting the number of seedlings along two randomly placed meter sticks for each row of each plot. The mean number of seedlings per meter of row was determined for each treatment. Seedling counts were conducted on 27 June 1984.

Quantitative species composition data for each plot was collected on 10 August 1984. The herbaceous plants were sampled by the ten pin point frame method (Levy and Madden 1933, Tinney, Aamodt, and Ahlgren 1937, Heady and Rader 1958 and Smith 1959). Fifteen hundred points were read for each treatment (500 points per plot). A systematic sampling scheme was used for each plot. A permanent major transect was established three feet inside and parallel to the east boundary of each plot. Five minor transects were established perpendicular to the major transect at nine foot intervals starting nine feet from the south boundary of the plot. One hundred points were read on each minor transect equally spaced across the plot.

Forb and shrub densities were sampled by the use of one tenth meter square quadrats on 28 August 1984. The forbs and shrubs that were rooted within the frame were counted by species in each of the 25 quadrats per plot. Five 0.1 m² quadrats were spaced at 6 foot intervals along each of the five minor transects.

Alfalfa Interseeding Row Spacing Techniques Trial

Location:	Dickinson Experiment Station Ranch Headquarters NE $\frac{1}{4}$, NW $\frac{1}{4}$, SW $\frac{1}{4}$ Sec. 23, T. 143 N., R. 96 W.
Replications:	Three Randomized Block Design
Study Size:	183' x 241' 1.01 acres
Plot Size:	33' x 50' 0.04 acres
Perimeter border:	10' on west and south, 3' on north and 0' on east
Alleys:	10'
Soil:	Vebar
Range Site:	Sandy with a few thin claypan sites
Seeding Date:	21 Apr 1983
Seeding Rate:	0.50 lbs. PLS/row/acre
Alfalfa Variety:	Travois
Chisel Plow Shovel:	4" twisted
Row Spacings:	0, 2, 3, 4, 5, 8 and 10 foot

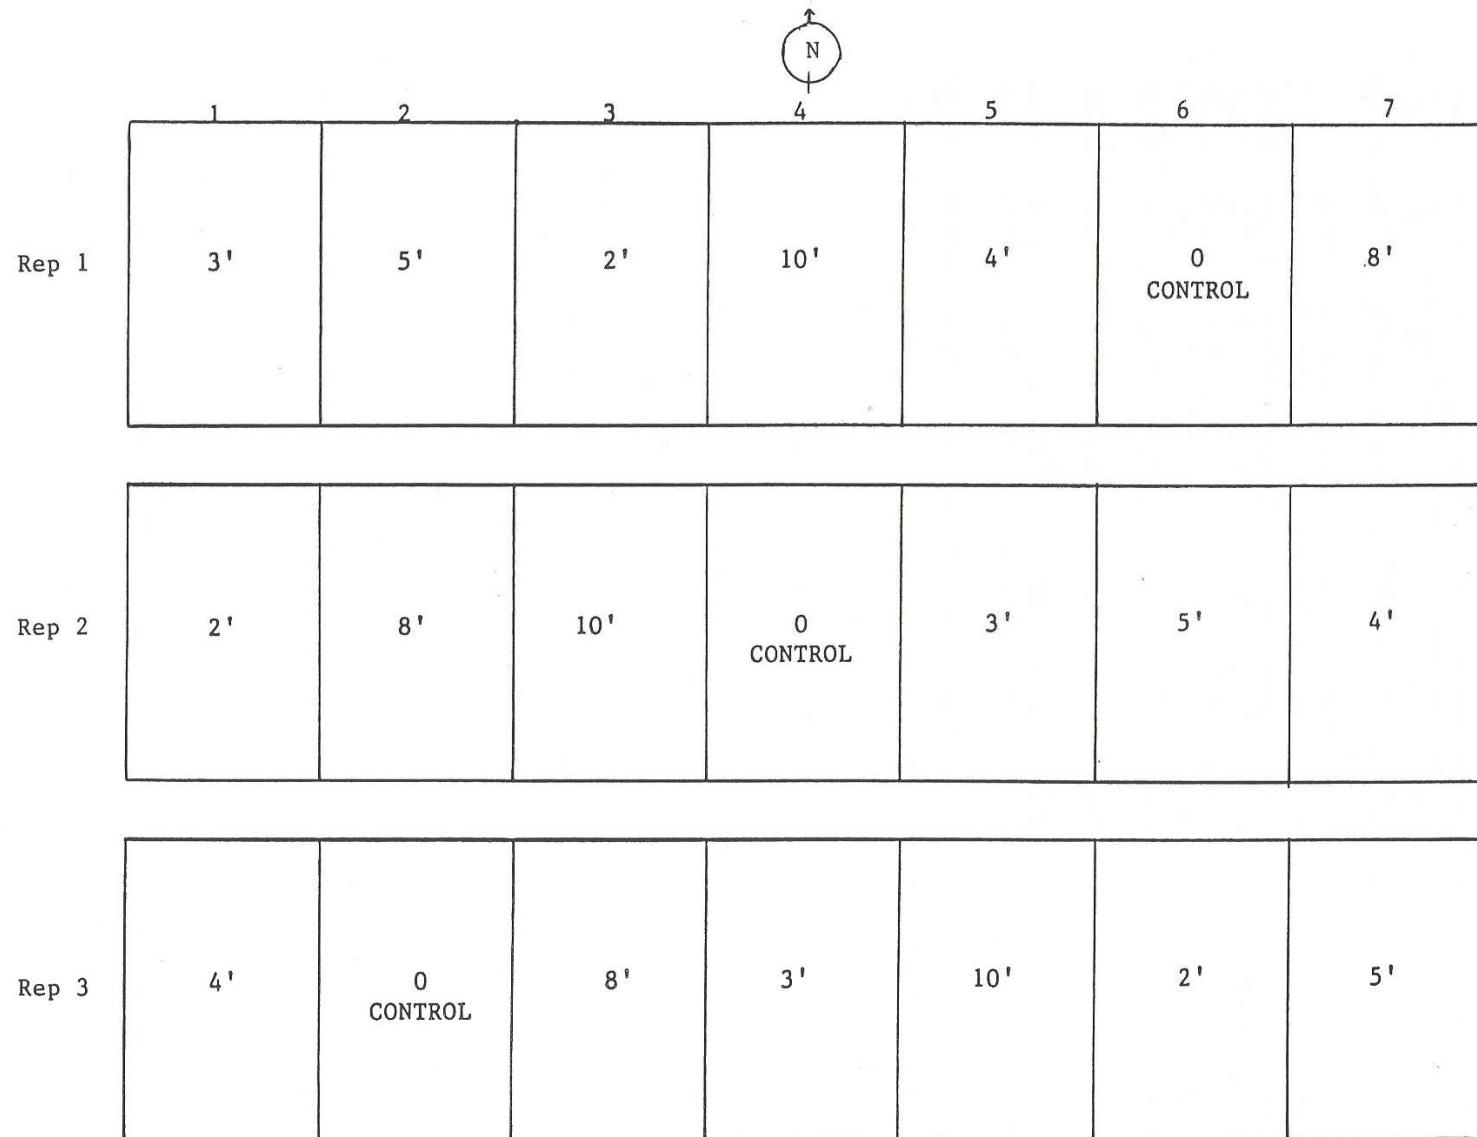

Figure 1. Alfalfa interseeding row spacing techniques trial with 0, 2, 3, 4, 5, 8 and 10 foot row spacings, seeded 21 Apr 1983.

ALFALFA INTERSEEDING FURROW WIDTH TECHNIQUES TRIAL

This trial was designed to evaluate alfalfa interseeding into rangeland with different widths of the furrow openings. The intended purpose of the data will be primarily to assist in the determination of a recommended furrow width for alfalfa interseeding into rangeland for pasture use in western North Dakota.

These plots were established on 0.60 acres located on the NE $\frac{1}{4}$, NW $\frac{1}{4}$, SW $\frac{1}{4}$ Sec. 23, T. 143 N., R. 96 W. at the ranch headquarters of the Dickinson Experiment Station. The 33 x 50 foot plots were arranged in a randomized block design with three replications. The soil was vebar fine sandy loam. The range site was sandy with a few thin claypan sites. Travois alfalfa was seeded at a rate of 0.50 lbs PLS/row/acre on 21 April 1983. A three foot row spacing was used. Two inch straight, three inch twisted and four inch twisted chisel plow shovels were used as the furrow openers. A control plot of no interseeding was included in each replication.

The data that were collected from these plots were: above ground herbage production separated into nine categories, alfalfa seedling counts per meter of row, species composition by point frame and forb densities by use of one tenth meter square quadrats.

The above ground herbage production was sampled by clipping the vegetation to ground level in two $\frac{1}{4}$ m² quadrats for each plot on 22 June 1984. The herbage was separated into nine categories, cool short, warm short, cool mid, western wheatgrass, warm mid, warm tall, sedge, forbs and shrubs. The samples were oven dried at 80°C. The average herbage production for each category and the total production for each plot were determined. The reported figures are means of the three replications for each treatment.

The alfalfa seedling counts were made by counting the number of seedlings along two randomly placed meter sticks for each row of each plot. The mean number of seedlings per meter of row was determined for each treatment. Seedling counts were conducted on 27 June 1984.

Quantitative species composition data for each plot was collected on 10 August 1984. The herbaceous plants were sampled by the ten pin point frame method (Levy and Madden 1933, Tinney, Aamodt, and Ahlgren 1937, Heady and Rader 1958, and Smith 1959). Fifteen hundred points were read for each treatment (500 points per plot). A systematic sampling scheme was used for each plot. A permanent major transect was established three feet inside and parallel to the east boundary of each plot. Five minor transects were established perpendicular to the major transect at nine foot intervals starting nine feet from the south boundary of the plot. One hundred points were read on each minor transect equally spaced across the plot.

Forb and shrub densities were sampled by the use of one tenth meter square quadrats on 28 August 1984. The forbs and shrubs that were rooted within the frame were counted by species in each of the 25 quadrats per plot. Five 0.1 m² quadrats were spaced at 6 foot intervals along each of the five minor transects.

Alfalfa Interseeding Furrow Width Techniques Trial

Location:	Dickinson Experiment Station Ranch Headquarters NE $\frac{1}{4}$, NW $\frac{1}{4}$, SW $\frac{1}{4}$ Sec. 23, T. 143 N., R. 96 W.
Replications:	Three Randomized Block Design
Study Size:	183' x 142' 0.60 acres
Plot Size:	33' x 50' 0.04 acres
Perimeter border:	10' on east and south, 3' on north and 0' on west
Alleys:	10'
Soil:	Vebar
Range Site:	Sandy with a few thin claypen sites
Seedling Date:	21 Apr 1983
Seedling Rate:	0.50 lbs. PLS/row/acre
Alfalfa Variety:	Travois
Row Spacing:	3'
Chisel Plow Shovels:	0", 2", 3" twisted and 4" twisted

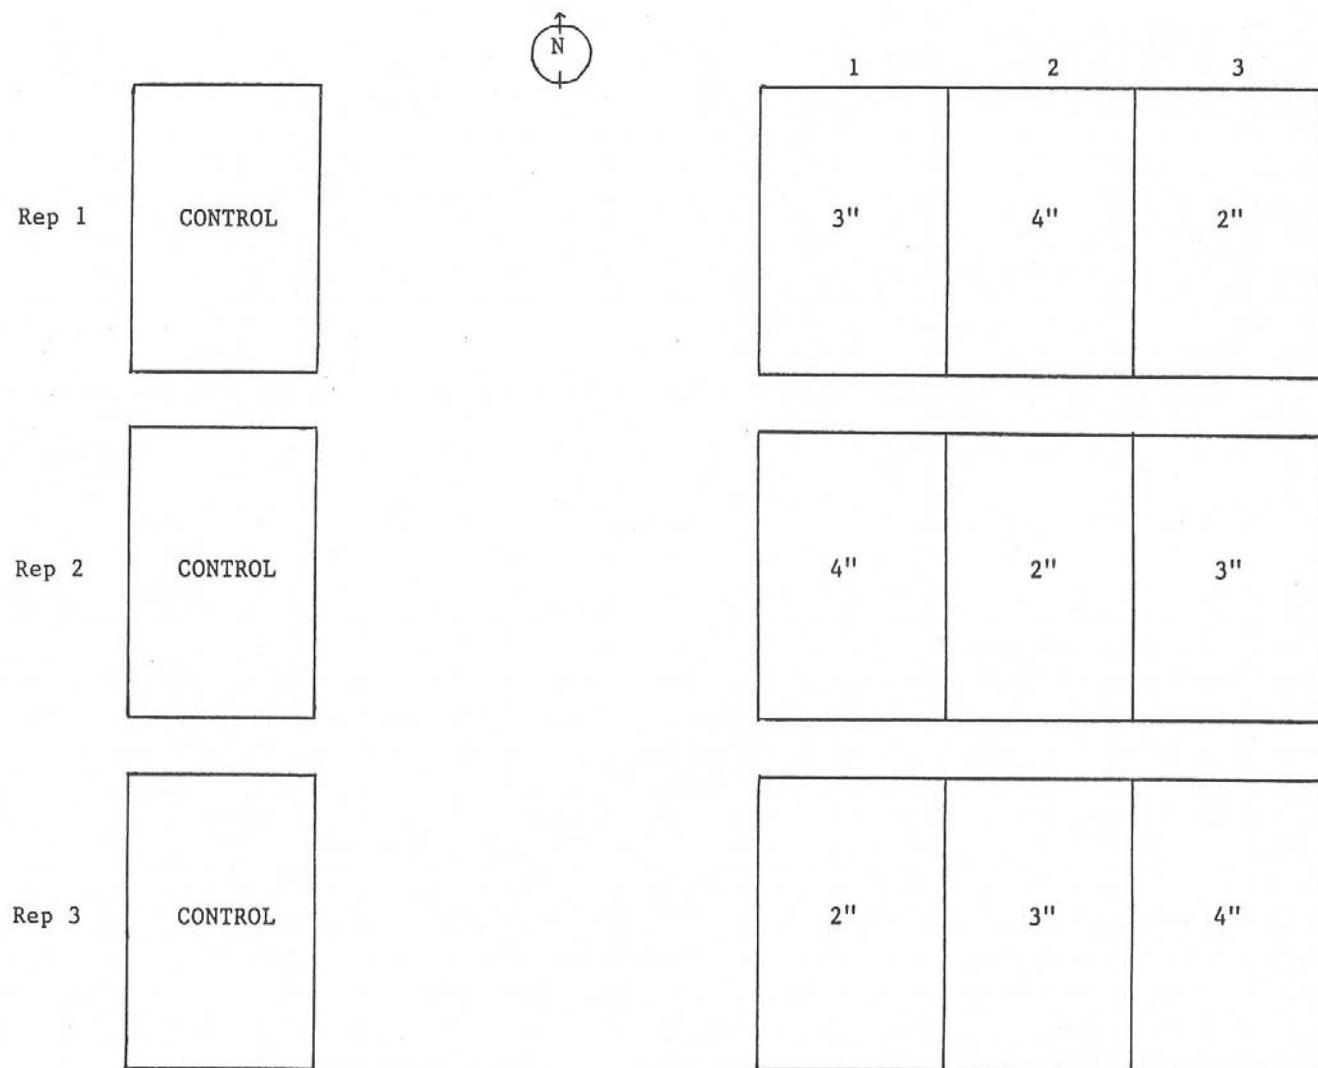

Figure 2 . Alfalfa interseeding furrow width techniques trial using 2, 3 and 4 inch chisel plow shovels, seeded 21 Apr 1983.

INTERSEEDED ALFALFA VARIETY RESPONSE TO GRAZING TRIAL

This trial is designed to evaluate the response to grazing pressure at three different time periods of seven pasture type alfalfa varieties and one hay type alfalfa variety which is used as a control. The purpose of this trial is to help determine which alfalfa variety or varieties are suitable for interseeding into rangeland for pasture use. This trial will also test if season of use causes a difference in growth and herbage production from the different varieties.

These plots were established on 13 acres located on the S $\frac{1}{2}$, SE $\frac{1}{4}$, SW $\frac{1}{4}$ Sec. 23, and SW $\frac{1}{4}$, SW $\frac{1}{4}$, SE $\frac{1}{4}$ Sec. 23, T. 140 N., R. 97 W. at the Dickinson Experiment Station. The 48 x 390 foot plots were arranged in a randomized block design with three replications. Each plot was split equally into three grazing treatments of 30 days each for June, July and August. The soils were vebar fine sandy loam, morton silt loam and regent silty clay loam. The range sites were sandy, silty and clayey. The alfalfa varieties that were included were Anik, Drylander, Kane, Prowler, Ranglander, Spredor II, Travois and Vernal. Each variety was seeded on 27 and 28 April 1983 at the rate of 0.50 lbs PLS/row/acre, using three foot row spacing and three inch twisted chisel plow shovels as the furrow openers.

The data that were collected from these plots were: above ground herbage production and alfalfa seedling counts. The above ground herbage production was sampled by clipping the vegetation to ground level in three $\frac{1}{4}$ m 2 quadrats for each plot on 5 July 1984. The herbage was separated into graminoids, forbs, and shrubs. The samples were oven dried at 80°C. The average herbage production for each category and the total production for each plot were determined. The reported data are means of the three replications for each treatment.

The alfalfa seedling counts were made by counting the number of seedlings along three randomly placed meter sticks for each row of each plot. The mean number of seedlings per meter of row was determined for each treatment. Seedling counts were conducted on 12 July 1984.

Interseeded Alfalfa Variety Response to Grazing Trial

Location:	Dickinson Experiment Station S $\frac{1}{2}$, SE $\frac{1}{4}$, SW $\frac{1}{4}$ Sec. 23, T. 140 N., R. 97 W. and SW $\frac{1}{4}$, SW $\frac{1}{4}$, SE $\frac{1}{4}$ Sec. 23, T. 140 N., R. 97 W.
Replications:	Three Split Plot Design
Study Size:	392' x 1480' 13.32 acres
Plot Size:	48' x 390' 0.43 acres
Drainage:	3.16 acres
Soils:	Vebar, Morton and Regent
Range Sites:	Sandy, Silty and Clayey
Seedling Date:	27-28 Apr 1983
Seeding Rate:	0.50 lbs. PLS/row/acre
Row Spacing:	3'
Chisel Plow Shovel:	3" twisted
Alfalfa Varieties:	Anik, Drylander, Kane, Prowler, Rangelander, Spredor II, Travois and Vernal.
Split Treatments:	Three 30 day grazing periods June, July and August

**Plant Species List of the Alfalfa Interseeding Trial
At the Dickinson Experiment Station, 1984**

Graminoids:

An sc	Andropogon scoparius	Little bluestem
Ag sm	Agropyron smithii	Western wheatgrass
Ag tr	Agropyron trachycaulum	Slender wheatgrass
Ar lo	Aristida longiseta	Red threeawn
Bo gr	Bouteloua gracilis	Blue grama
Bu da	Buchloe dactyloides	Buffalo grass
Ca mo	Calamagrostis montanensis	Plains reedgrass
Ca lo	Calamovilfa longifolia	Prairie sandreed
Ko py	Koeleria pyramidata	Prairie junegrass
Mu cu	Muhlenbergia cuspidata	Plains muhly
Mu sq	Munroa squarrosa	False buffalo grass
Pa ol	Panicum oligosanthes	Scribner panic grass
Po pr	Poa pratensis	Kentucky bluegrass
St co	Stipa comata	Needleandthread
St vi	Stipa viridula	Green needlegrass
Ca el	Carex eleocharis	Needleleaf sedge
Ca fi	Carex filifolia	Threadleaved sedge
Ca he	Carex heliophila	Yellow sedge

Forbs:

Ac mi	Achillea millefolium	Yarrow
Al st	Allium textile	White wild onion
Am re	Amaranthus retroflexus	Rough pigweed
An oc	Androsace occidentalis	Fairy candelabra
An ne	Antennaria neglecta	Pussytoes
An pa	Antennaria parvifolia	Pussytoes
Ar ho	Arabis holboellii	Slim rockcress
Ar dr	Artemisia dracunculus	Green sage
Ar fr	Artemisia frigida	Fringed sage
Ar lu	Artemisia ludoviciana	White sage

Forbs (Continued):

As er	Aster ericoides	White prairie aster
As la	Aster laevis	Smooth blue aster
As ob	Aster oblongifolius	Aromatic aster
As pt	Aster ptarmicoides	White upland aster
As ca	Astragalus canadensis	Little rattlepod
As cr	Astragalus crassicarpus	Ground plum
As tr	Astragalus trifyllus	Tufted milkvetch
Ce ar	Cerastium arvense	Prairie chickweed
Ch al	Chenopodium album	Lamb's quarters
Ch vi	Chrysopsis villosa	Golden aster
Ci un	Cirsium undulatum	Prairie thistle
Co um	Commandra umbellata	Bastard toadflax
Co ar	Convolvulus arvensis	Field bindweed
Co se	Convolvulus sepium	Large bindweed
Co ca	Conyza canadensis	Horseweed
Ec an	Echinacea angustifolia	Purple coneflower
Er as	Erysimum asperum	Western wallflower
Eu di	Euphorbia dictyosperma	Spurge
Eu ge	Euphorbia geyeri	Geyer's spurge
Ga bo	Galium boreale	Northern bedstraw
Ga co	Gaura coccinea	Gaura
Gl le	Glycyrrhiza lepidota	Wild licorice
Gr sq	Grindelia squarrosa	Gunweed
Gu sa	Gutierrezia sarothrae	Broomweed
Ha sp	Haplopappus spinulosus	Spiny ironweed
He hi	Hedeoma hispida	Rough pennyroyal
He an	Helianthus annuus	Common sunflower
He ri	Helianthus rigidus	Stiff sunflower
Ko sc	Kochia scoparia	Kochia
La ob	Lactuca oblongifolia	Blue wild lettuce
La se	Lactuca serriola	Prickly lettuce
Le de	Lepidium densiflorum	Peppergrass
Li pu	Liatris punctata	Blazing star

Forbs (Continued):

Li ri	<i>Linum rigidum</i>	Stiffstem flax
Li in	<i>Lithospermum incisum</i>	Narrow-leaved pucooon
Lo am	<i>Lotus americanus</i>	Prairie bird's foot trefoil
Ly ju	<i>Lygodesmia juncea</i>	Skeleton weed
Me fa	<i>Medicago falcata</i>	Travois alfalfa
Me of	<i>Melilotus officinalis</i>	Yellow sweetclover
Mu di	<i>Musineon divaricatum</i>	Wild parsley
Ne pa	<i>Neslia paniculata</i>	Ball mustard
Oe bi	<i>Oenothera biennis</i>	Common evening primrose

ALFALFA INTERSEEDED PASTURE GRAZING TRIAL - 1984
DICKINSON EXPERIMENT STATION

L. Manske

The alfalfa interseeded pasture grazing trial was seeded in May of 1977. A pasture type alfalfa (Travois) was interseeded into 10 acres of mixed grass prairie using a mechanical sod control method. The seeding rate was 4 pounds per acre. An 18 acre pasture with no treatment was used as the control. The number of cow-calf pairs grazed in the pastures varied from year to year (10 in 1978, 1979, and 1982, 8 in 1981 and 1984, and 7 in 1980) but the number remained constant on both pastures. The alfalfa interseeded pasture was not grazed in 1982 and data was not collected on either pasture in 1983. Stocking rates varied by pasture size and length of grazing period.

The soils of the pastures were fine sandy loams. These soils were predominantly sandy range sites.

The species composition was mixed grass prairie dominated with blue grama (Bouteloua gracilis), sun sedge (Carex heliophila), prairie junegrass (Koeleria pyramidata), western wheatgrass (Agropyron smithii), and needleandthread (Stipa comata).

Herbage production was determined by clipping the vegetation to ground level inside one-third meter square quadrats both inside and outside exclosure cages. The herbage samples were then oven dried at 175°F (80°C) and weighted to give oven dried above ground herbage production.

Cow and calf performance was determined by individual weight gains or losses. Cattle were weighted on and off each pasture. These data were converted into mean weight gain in pounds per day per head and mean weight gain in pounds per day per acre for the calves and cows.

Herbage production for the alfalfa interseeded and control pastures are included in Table 1. The mean total herbage production was 1246 and 3694 pounds per acre for the untreated control and alfalfa interseeded pastures respectively. Interseeding alfalfa increased the mean total herbage production by 196.4% above the untreated control. The alfalfa comprised 71% of the total.

Animal performance for the alfalfa interseeded and control pastures are included in Table 2. Calf daily gains per head were good on both the alfalfa interseeded and control pastures with 2.27 and 2.01 pounds respectively. The calf daily gains per head were 13% greater on the alfalfa interseeded pasture. The calf daily gains per acre were 1.81 and 0.89 pounds on the alfalfa interseeded and control pastures respectively. This gain per acre was 103% greater on the alfalfa interseeded pasture.

Cow performance on the alfalfa interseeded pasture was good with a daily gain per head of 1.11 pounds and a daily gain per acre of 0.89 pounds. The mean daily gain per head was 0.16 pounds and the mean daily gain per acre was 0.07 pounds for the cows on the control pasture. Generally cows lose weight on native range pastures in western North Dakota after 15 August. Five of the 8 cows on the control pasture lost an average of 0.51 pounds per day for the 36 day grazing period. The other 3 cows gained weight at the rate of 1.27 pounds per day. All of the eight cows on the alfalfa interseeded pasture gained weight for the same grazing period.

The stocking rates for the alfalfa interseeded and control pastures were 0.94 and 0.52 AUM's per acre respectively. The stocking rate was 81% greater on the alfalfa interseeded pasture. The mean stocking rate from 1978 to 1984 has been increased by 41% on the alfalfa interseeded pasture over the control pasture.

Interseeding of alfalfa into native range pastures shows considerable promise as a management tool for western North Dakota. The alfalfa interseeded pasture has greater herbage production, greater calf and cow gains per head and per acre, and higher stocking rates than the control native range pasture.

ALFALFA VARIETY TRIAL, 1980 - 1984

Dickinson Experiment Station
L. Manske and H. Goetz

An alfalfa variety trial was seeded at the Dickinson Experiment Station in May 1979. The 10 x 25 foot plots were arranged in a randomized block design with four replications. The trial was designed to evaluate the performance of the varieties in western North Dakota on the basis of dry weight herbage production and compared to a standard variety (Vernal). Four pasture type, sixteen dryland hay type and one hay and pasture type varieties were included in the trial. One cutting in late June or early July has been made annually since 1980.

The annual above ground dry weight herbage production for each variety and the percentage of production compared to a standard variety (Vernal) are shown in Table 1. The five highest producing varieties for 1980 were Norseman, Ranger, Kane, Iroquois, and Rangelander with 445, 403, 402, 401 and 400 pounds of herbage production per acre respectively. The five highest producing varieties for 1981 were Anik, D-111, Baker, Kane, and Rangelander with 1978, 1747, 1662, 1655, and 1642 pounds of herbage per acre. The five highest producing varieties for 1982 were Kane, Spredor II, Norseman, Travois, and Rangelander with 6139, 5260, 5210, 5077 and 4981 pounds of herbage production per acre respectively. The five highest producing varieties for 1983 were 520, Kane, 524, Baker and D-111 with 6342, 6135, 5896, 5865 and 5442 pounds per acre of herbage production respectively. The five highest producing varieties for 1984 were Norseman, Ladak-65, Rangelander, Polar I and Thor with 4899, 4884, 4755, 4607 and 4554 pounds per acre of herbage production respectively.

The production data from this trial has shown that there was very little difference between most of the alfalfa varieties that were included. The five year (1980-1984) mean annual production for all the varieties was 3150 pounds per acre. The five varieties with the greatest five year mean annual production were Kane (3752 lbs/acre), Ladak 65 (3369 lbs/acre), Rangelander (3358 lbs/acre), Norseman (3322 lbs/acre) and 520 (3273 lbs/acre). The two varieties with the lowest five year mean annual production were Agate (2636 lbs/acre) and Trek (2933 lbs/acre). The standard variety (Vernal) ranked thirteenth out of twenty one varieties with a five year mean annual production of 3112 lbs/acre.

The five year mean production for the pasture type varieties was 3341 lbs/acre. This was 7.4 percent greater than mean production for the hay type varieties which was 3115 lbs/acre (Table 2). The pasture type varieties have had a slightly greater production than the hay type varieties each year of the trial (Table 2).

The alfalfa varieties were separated into three winterhardy categories based on their reported adaptability to survive the winter period. These categories were: very winterhardy, winterhardy, and moderately winterhardy. All of the pasture type alfalfas were very winterhardy. Three of the dryland hay type varieties were very winterhardy, one variety was moderately winterhardy and twelve hay type varieties were winterhardy. One variety was a hay and pasture type. This hay and pasture type variety was very winterhardy. The five year mean production for the very winterhardy, the winterhardy and the moderately winterhardy categories were 3238, 3101 and 3042 pounds per acre respectively (Table 3). The very winterhardy category had the greatest herbage production in 1980, 1982 and the five year mean. The winterhardy category had the greatest herbage production in 1983. The moderately winterhardy category had the greatest production in 1981 and 1984 but it has had the lowest production in 1980, 1982, 1983 and the five year mean (Table 3).

Most of the varieties in the trial performed satisfactorily under the environmental conditions of western North Dakota during this trial. Twelve of the twenty one varieties had greater five year mean annual herbage production than the standard variety (Vernal). All of the varieties had five year mean production of over 3300 lbs/acre. Two of these varieties were pasture types and the other two were hay types. Three of the four were very winterhardy and one was winterhardy.

Most of the varieties have had very good herbage production during the 1982, 1983 and 1984 growing seasons. Fifteen varieties have three year mean annual herbage production of over 4500 lbs/acre, six varieties have over 4800 lbs/acre, and two varieties have over 5000 lbs/acre. The six varieties with the greatest three year (1982-1984) mean annual herbage production were Kane, Ladak 65, Rangelander, 520, Norseman, and Polar I with 5567, 5034, 4910, 4901, 4870 and 4860 pounds per acre respectively.

Plant density and mean dry weight per plant data were collected in 1983 and 1984 for each variety (Table 4). The five varieties with the greatest number of plants per square foot were Anik, Rangelander, Kane, Spredor II and Ramsey with 3.92, 3.87, 3.64, 3.53 and 3.45 plants per foot squared respectively. The five varieties with the lowest plant densities were Trek, Polar I, D-111, Thor and 520 with 2.59, 2.61, 2.71, 2.88 and 2.93 plants per foot squared respectively. The five varieties with the greatest mean weight per plant were Polar I, 520, Thor, D-111 and Trek with 0.72, 0.67, 0.66, 0.63 and 0.62 ounces per plant respectively. The four varieties with the lowest mean plant weight were Anik, Rangelander, Agate and Ramsey with 0.45, 0.46, 0.47 and 0.49 ounces per plant respectively. Generally the varieties with the higher plant densities had the lower mean plant dry weights and the varieties with the lower plant densities had the greatest mean plant weights.

Plant densities for the pasture type and dryland hay type varieties (Table 5) were 3.60 and 3.06 plants per foot squared respectively. The mean weight per plant for the pasture and hay type varieties were 0.50 and 0.58 ounces respectively. The pasture type alfalfa varieties had a slightly greater plant density per foot squared, a slightly lower mean weight per plant and a slightly greater herbage production per acre than the hay type alfalfa varieties.

The plant densities for the very winterhardy, the winterhardy, and the moderately winterhardy categories were 3.52, 3.02 and 2.88 respectively (Table 6). The mean weight per plant for the very winterhardy, the winterhardy, and the moderately winterhardy categories were 0.51, 0.58 and 0.66 ounces respectively (Table 6). The very winterhardy varieties had the greatest plant density per foot squared, the lowest mean weight per plant and the greatest mean herbage production per acre. The moderately winterhardy varieties had the lowest plant density, the greatest mean plant weight and the lowest mean herbage production per acre. The winterhardy varieties were intermediate between the very winterhardy varieties and the moderately winterhardy varieties in plant density, mean plant weight and herbage production per acre.

Most of the varieties in the trial performed very similarly. There was very little actual significant difference between the performance of any of the varieties. Only one variety (Kane) has had an annual mean herbage production of significant difference from the standard variety (Vernal). Vernal has performed satisfactorily in western North Dakota and any variety selected to be seeded should have tested performance as good or better than Vernal. These plots were established in 1979 and have been stressed by drought conditions. Western North Dakota is subjected to drought and harsh winter conditions on an irregular basis. These conditions should be considered when selecting alfalfa varieties.

ALFALFA VARIETY TRIAL, 1982 - 1984

Hettinger Experiment Station

L. Manske and H. Goetz

An alfalfa variety trial was seeded at the Hettinger Experiment Station in May 1981. The 10 x 25 foot plots were arranged in a randomized block design with three replications. The alleys between the replications were five feet wide. The trial was designed to evaluate the performance of the varieties in southwestern North Dakota on the basis of dry weight herbage production and compared to a standard variety (Vernal). Six pasture type, nineteen dryland hay type and two hay and pasture type varieties were included in the trial. One cutting in late June or early July has been made annually since 1982.

The annual above ground dry weight herbage production for each variety and the percentage of production compared to a standard variety (Vernal) are shown in Table 1. The five highest producing varieties for 1982 were Prowler, Travois, Spredor II, Nugget, and Iroquois with 5244, 5191, 4986, 4790 and 4782 pounds of herbage production per acre respectively. The five highest producing varieties for 1983 were Nugget, Drylander, Prowler, Ladak 65 and Spredor II with 6071, 5528, 5212, 5114 and 5079 pounds per acre of herbage production respectively. The five highest producing varieties for 1984 were Spredor II, Drylander, Norseman, Vernal and Travois and D-111 with 4564, 4267, 3848, 3619 and 3509 pounds per acre of herbage production respectively.

The production data from this trial has shown that there was very little difference between most of the alfalfa varieties that were included. The three year (1982-1984) mean annual production for all the varieties was 4047 pounds per acre. The five varieties with the greatest three year mean annual production were Spredor II (4876 lbs/acre), Drylander (4800 lbs/acre), Nugget (4611 lbs/acre), Prowler (4545 lbs/acre) and Ladak 65 (4284 lbs/acre). The standard variety (Vernal) ranked twentieth out of twenty seven varieties with a three year mean annual production of 3841 lbs/acre.

The three year mean production for the pasture type varieties was 4368 lbs/acre. This was 10.2 percent greater than mean production for the hay type varieties which was 3964 lbs/acre (Table 2). The pasture type varieties have had a slightly greater production than the hay type varieties each year of the trial (Table 2).

The alfalfa varieties were separated into three winterhardy categories based on their reported adaptability to survive the winter period. These categories were: very winterhardy, winterhardy, and moderately winterhardy. All of the pasture type alfalfas were very winterhardy. Two of the dryland hay type varieties were very winterhardy, five varieties were moderately winterhardy and twelve hay type varieties were winterhardy. Two varieties were hay and pasture type varieties. One of these hay and pasture type varieties was winterhardy and the other was moderately winterhardy. The three year mean production for the very winterhardy, the winterhardy and the moderately winterhardy categories were 4255, 4050 and 3765 pounds per acre respectively (Table 3). The very winterhardy category had the greatest mean herbage production for each year of this trial. The moderately winterhardy category had the lowest mean herbage production in each year.

All of the varieties in the trial performed satisfactorily under the environmental conditions of southwestern North Dakota during this trial. All of the varieties had three year mean herbage production of greater than 3500 lbs/acre. Four varieties had three year mean production of over 4500 lbs/acre.

Plant density and mean dry weight per plant data were collected in 1983 and 1984 for each variety (Table 4). The five varieties with the greatest number of plants per square foot were Magnum, Ladak 65, 520, 532 and Ranger with 4.99, 4.34, 4.25 and 4.19 plants per foot squared respectively. The five varieties with the lowest plant densities were Polar I, Drylander, Trek, D-111 and Kane with 3.04, 3.38, 3.44, 3.50 and 3.51 plants per foot squared respectively. The five varieties with the greatest mean weight per plant were Drylander, Polar I, Spredor II, D-111 and Perry with 0.65, 0.47, .046, 0.43 and 0.43 ounces per plant respectively. The four varieties with the lowest mean plant weight were Magnum, AS-67, 532 and 520 with 0.25, 0.28, 0.31 and 0.33 ounces per plant respectively. Generally the varieties with the higher plant densities had the lower mean plant dry weights and the varieties with the lower plant densities had the greater mean plant weights.

Plant densities for the pasture type and dryland hay type varieties (Table 5) were 3.71 and 3.84 plants per foot squared respectively. The mean weight per plant for the pasture and hay type varieties were 0.45 and 0.37 ounces respectively. The pasture type alfalfa varieties had a slightly lower plant density per foot squared, a slightly greater mean weight per plant and a slightly greater herbage production per acre than the hay type alfalfa varieties.

The plant densities for the very winterhardy, the winterhardy, and the moderately winterhardy categories were 3.71, 3.77 and 4.08 respectively (Table 6). The mean weight per plant for the very winterhardy, the winterhardy, and the moderately winterhardy categories were 0.43, 0.39 and 0.33 ounces respectively (Table 6). The very winterhardy varieties had the lowest plant density per foot squared, the greatest mean weight per plant and the greatest herbage production per acre. The moderately winterhardy varieties had the greatest plant density, the lowest mean plant weight and the lowest herbage production per acre. The winterhardy varieties were intermediate between the very winterhardy varieties and the moderately winterhardy varieties in plant density, mean plant weight and herbage production per acre.

Most of the varieties in the trial performed very similarly. There was very little actual significant difference between the performance of any of the varieties. Only three varieties have had annual mean herbage production of significant difference from the standard variety (Vernal). Vernal has performed satisfactorily in western North Dakota and any variety selected to be seeded should have tested performance as good or better than Vernal. These plots were established in 1981 and have not been severely stressed by drought conditions nor harsh winter conditions. Southwestern North Dakota is subjected to drought and harsh winter conditions on an irregular basis. These conditions should be considered when selecting alfalfa varieties.

BROMEGRASS VARIETY TRIAL

Dickinson Experiment Station – 1984

L. Manske and H. Goetz

A bromegrass variety trial was seeded at the Dickinson Experiment Station in the spring of 1979. The 10x25 foot plots were arranged in a randomized block design with four replications. Eleven varieties of smooth bromegrass (Bromus inermis) and one selection of meadow bromegrass (Bromus biebersteinii) were included in the trial. The trial was designed to evaluate the performance of the varieties in western North Dakota on the basis of dry weight above ground herbage production.

The annual dry weight above ground herbage production for each variety is shown in Table 1. The four highest producing bromegrass varieties in 1984 were Barton, Lancaster, Meadow brome, and Baylor with 1784, 1765, 1580, and 1541 pounds of herbage production per acre respectively. The four varieties with the greatest five year (1980-1984) mean annual herbage production were Baylor, Lancaster, Meadow brome and Rebound with 2175, 2030, 2018 and 2000 pounds per acre respectively. The two varieties with the lowest five year mean herbage production were Mandan 404 and Manchar with 1569 and 1658 pounds per acre respectively.

The bromegrass varieties in this trial have performed satisfactorily under the environmental conditions of western North Dakota. Ten varieties of smooth bromegrass and the selection of meadow bromegrass have had five year mean annual herbage production of over 1600 lbs/acre, seven varieties have had production of over 1800 lbs/acre and four varieties have had mean annual production of over 2000 lbs/acre. The top producing bromegrass varieties show good potential for use as tamegrass pastures and hayland in western North Dakota.

Leafy Spurge Control with Tebuthiuron – 1984

Dickinson Experiment Station

Llewellyn Manske

A study that tests the effects of tebuthiuron (Graslan) on leafy spurge (Euphorbia esula) was started in 1983 at the Dickinson Experiment Station. Leafy spurge is a major problem weed in uncultivated rangelands in North Dakota. It greatly reduces herbage production and beef production which causes substantial economic losses. The leafy spurge plant is extremely difficult to control and has numerous mechanisms to survive control attempts.

Tebuthiuron is a herbicide that is primarily intended for use on shrubs in rangeland. The chemical is absorbed by the roots and translocated to the leaves. Photosynthesis is restricted. The leaves senesce prematurely and fall off and a new set of leaves develop. This process continues until the plant depletes its stored carbohydrates. The process may take one to four years before the plant dies completely depending on the species and the environmental conditions. In theory, this appears to be a desirable method to control leafy spurge.

One set of test plots for this study was established in 1983 on 0.1 acres located on the NE $\frac{1}{4}$, NE $\frac{1}{4}$, SW $\frac{1}{4}$ sec. 22, T. 141 N., R. 104 W. on the property of Dale Maus, five miles north of Camels Hump Butte. The 10 x 53 foot plots were arranged in a randomized block design with two replications. The size of the leafy spurge patch was not sufficient for additional treatments or replications. The soil was vebar fine sandy loam. The range site was sandy. The site has a slight slope of about 3% with an east aspect and the south half of the plots has a slight slope of about 5% with a north aspect. The vegetation on the site was predominantly leafy spurge with an understory of Kentucky bluegrass (Poa pratensis) and a few scattered plants of smooth bromegrass (Bromus inermis).

A second set of plots was established in 1984 on 0.12 acres located on NE $\frac{1}{4}$, SE $\frac{1}{4}$, NE $\frac{1}{4}$ sec. 4, T. 140 N., R. 103 W. on the property of Cecil Adams, northeast of Camels Hump Butte in the Knutson Creek drainage. The 30 x 22 foot plots were arranged in a randomized block design with two replications. The soil was Havrelon silt loam. The range site was overflow. The vegetation on the site was predominantly leafy spurge with a few scattered plants of silver sage (Artemisia cana) and western wild rose (Rosa woodsii) and a very sparse understory of Kentucky bluegrass.

The herbicide, tebuthiuron, was furnished by the Elanco Products Company. The chemical was incorporated into solid clay pellets with 20% active ingredients. Three rates of the 20% concentration were used in this trial each year. The three rates were: 1, 2 and 3 pounds of active ingredient per acre. A control of no chemical treatment was included in each replication. No additional herbicide was added to the 1983 applied treatment plots in 1984. The herbicide was broadcast applied with a whirly-bird hand spreader on 12 July 1983 and 4 June 1984. The recommended optimum period to apply herbicides to leafy spurge is from mid-June until seed dispersal during hot, dry weather in July (Lym and Messersmith, 1983).

The data that were collected on the 1983 applied and the 1984 applied treatment plots in 1984 were: above ground herbage production, leafy spurge stem densities and mean weight per leafy spurge stem. The sample dates in 1984 were 5 June, 19 June, 6 July, 8 August, 6 September, 8 October, and 8 November. The above ground herbage production was sampled by clipping the vegetation to ground level in two $\frac{1}{4}$ m² quadrats for each plot. The herbage was separated into four categories, leafy spurge, grass, forbs, and shrubs. The samples were oven dried at 80°C. The average herbage production for each category and the total production for each plot were determined. The leafy spurge stem densities were conducted by counting all of the current years leafy spurge stems that were rooted within two $\frac{1}{4}$ m² quadrats per plot. These data were converted to stems per foot square. The mean dry weight per leafy spurge stem data was collected by counting the number of stems clipped during collection of the above ground herbage samples per $\frac{1}{4}$ m² and calculating the mean weight per stem from the leafy spurge herbage production data.

A new set of plots will be established for each of the next two years. No retreatment will be applied to the four sets of plots. The herbage production data, the leafy spurge stem density data and the mean dry weight per leafy spurge stem data will be collected from these plots for a total of six years in order to follow the effects of tebuthiuron on leafy spurge.

Tebuthiuron does have an effect on leafy spurge. The herbicide causes a reduction in herbage weight, stem density and mean weight per stem of leafy spurge.

The first set of plots were treated with 1, 2, and 3 lbs ai per acre in 1983. The reduction in herbage weight of leafy spurge at 422 days after treatment was 78%, 93% and 95% for the 1, 2, and 3 lbs ai/acre rates respectively. The control treatment had a reduction of 68% in herbage weight of leafy spurge during the same time period. The density of leafy spurge stems was reduced by 66%, 94%, and 99.6% for the 1, 2, and 3 lbs ai/acre rates respectively while the control stem densities were reduced by 40% in 422 days. The mean weight per stem was reduced by 66%, 74%, and 67% for the 1, 2, and 3 lbs ai/acre rates respectively in 422 days while the control weight per stem was reduced by 57%. The grass component was also effected by the Tebuthiuron at these rates. Very little grass growth occurred on these plots after treatment. The reduction in herbage weight of grass at 422 days after treatment was 52%, 66%, and 78% for the 1, 2, and 3 lbs ai/acre rates respectively. The control had no change in grass herbage production at 422 days after treatment.

The second set of plots were treated with 1, 2, and 3 lbs ai per acre in 1984. The reduction in herbage weight of leafy spurge at 93 days after treatment was 37%, 52%, and 69% for the 1, 2, and 3 lbs ai/acre rates respectively. The control treatment had a reduction of 5% in herbage weight of leafy spurge during the same time period. The density of leafy spurge stems was reduced by 47%, 43%, and 62% for the 1, 2, and 3 lbs ai/acre rates respectively while the control stem densities were reduced by 32% in 93 days. The mean weight per stem was reduced by 14% and 28% for the 2 and 3 lbs ai/acre rates respectively in 93 days. The mean weight per stem was increased by 5% and 24% for the 1 lb ai/acre rate and the control respectively in 93 days. There was very little grass on this set of plots. The small amount of grass that was present at the start of the trial was semidormant at 93 days after treatment. Some regrowth did occur. At 125 days after treatment the grass herbage production was 103 lbs, 29 lbs, 18 lbs, and 0 lbs per acre for the control, 1, 2, and 3 lbs ai/acre rates respectively.

The data from these two sets of plots do show encouraging trends on the detrimental effects of tebuthiuron on leafy spurge.

Leafy Spurge Control by Tebuthiuron Applied in 1983

Location:	NE $\frac{1}{4}$, NE $\frac{1}{4}$, SW $\frac{1}{4}$ Sec. 22, T. 141 N., R. 104 W. Property of Dale Maus
Replications:	Two Randomized Block Design
Study Size:	53' x 80' 0.1 acres
Plot Size:	10' x 53' 0.012 acres
Perimeter border:	2'
Soil:	Vebar fine sand loam
Range Site:	Sandy
Herbicide:	Tebuthiuron 20% concentrated pellets
Application Date:	12 July 1983
Treatments:	0 lbs ai/acre 1 lbs ai/acre 2 lbs ai/acre 3 lbs ai/acre

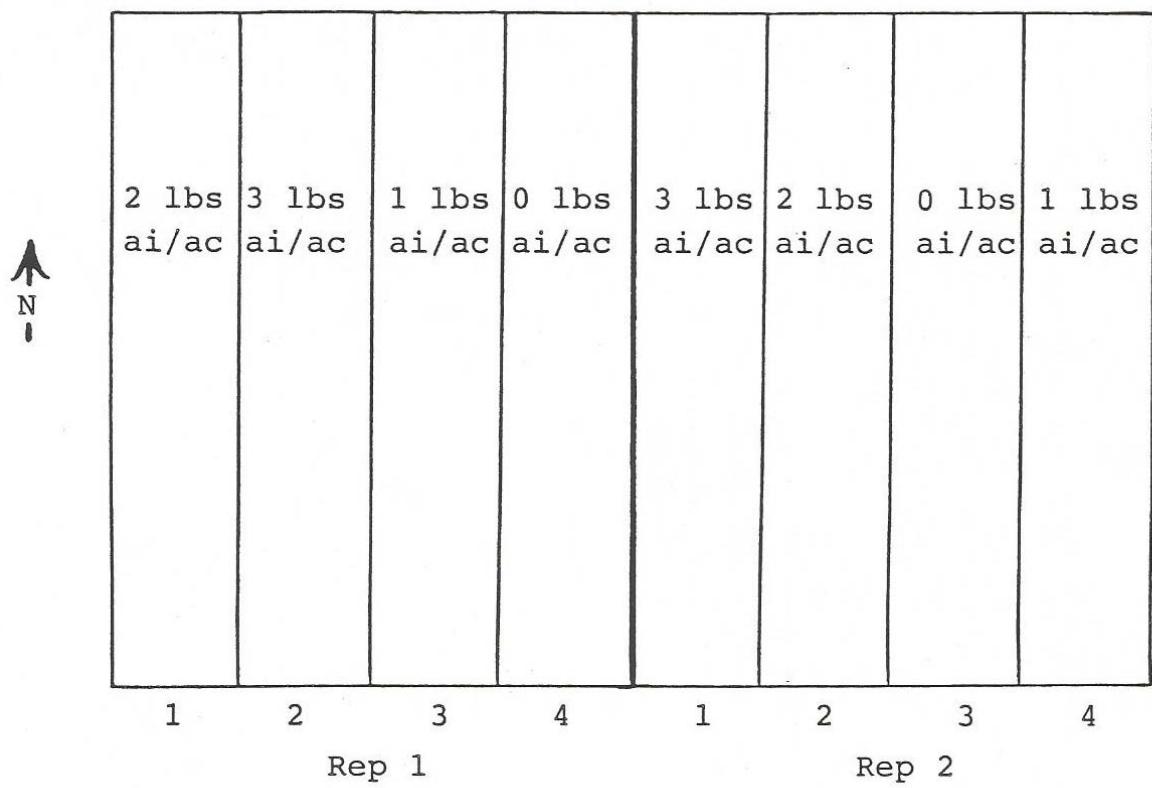

Figure 1. Control of Leafy Spurge with Tebuthiuron randomized block plot design with two replications. Rates are 0, 1, 2 and 3 pounds of active ingredient per acre using 20 percent concentration pellets. Located at NE $\frac{1}{4}$ NE $\frac{1}{4}$ SW $\frac{1}{4}$ sec. 22, T.141 N., R.104 W. Plots are 10 feet by 53 feet.

Leafy Spurge Control by Tebuthiuron Applied in 1984

Location: NE $\frac{1}{4}$, SE $\frac{1}{4}$, NE $\frac{1}{4}$ Sec. 4, T. 140 N., R. 103 W.
Property of Cecil Adams

Replications: Two Randomized Block Design

Study Size: 44' x 120' 0.12 acres
Plot Size: 22' x 30' 0.02 acres
Perimeter Border: 2'

Soil: Havrelon silt loam

Range Site: Overflow

Herbicide: Tebuthiuron
20% concentrated pellets

Application Date: 4 June 1984

Treatments:
0 lbs ai/acre
1 lbs ai/acre
2 lbs ai/acre
3 lbs ai/acre

Leafy Spurge Control with Chemical and Mechanical Treatments – 1984

Dickinson Experiment Station

Llewellyn Manske and Phillip Sjursen

A study to test the effects of chemical and mechanical treatments on leafy spurge (Euphorbia esula) was started in 1984 at the Dickinson Experiment Station. The chemical Picloram (Tordon) at 2 lbs ai / acre (1 gallon of 22K liquid or 100 pounds of 2K granules) has been shown by many scientists to reduce leafy spurge and it is one technique that is accepted and recommended as a good treatment for leafy spurge control. It is not an inexpensive treatment. The mechanical treatment of mowing leafy spurge has been observed to reduce the density of leafy spurge at times. Observations also have been made that spraying picloram on leafy spurge regrowth two weeks after mowing increases the effects of the chemical. These observations of the effects of mowing of leafy spurge need to be tested to determine if mowing has a beneficial detrimental effect on leafy spurge. If this study shows that mowing of leafy spurge can be beneficial or additive to chemical treatments, a follow-up study will be needed to test if the rate of chemical applied can be reduced.

The test plots were established on 0.25 acres located on the NE $\frac{1}{4}$, SE $\frac{1}{4}$, NE $\frac{1}{4}$ Sec. 4, T. 140 N., R. 103 W. on the property of Cecil Adams. The 30 x 22 foot plots were arranged in a randomized block design with two replications. The soil was Havrelon silt loam. The range site was overflow. The vegetation on the site was predominantly leafy spurge with a few scattered plants of silver sage (Artemisia cana) and wolfberry (Symphoricarpos occidentalis) and a thin understory of Kentucky bluegrass (Poa pratensis), prairie sandreed (Calamovilfa longifolia and needleandthread Stipa comata).

The treatments were: in early June, mowing, mowing plus Tordon, and Tordon; in early July, mowing, mowing plus Tordon and Tordon; and in mid August, Tordon. A control of no treatment was included in each replication. The early June, early July and mid August periods of treatment coincided with pre-flower, post flower (seed development) and early regrowth phenological stages of development for the leafy spurge plants respectively. The mowing treatment was conducted with a sickle bar mower and the herbage was raked off the plots. The chemical treatment was applied at a rate of 2 lbs ai / acre of picloram in the form of 2K granules with a hand held whirlybird spreador.

The data that were collected from these plots were: above ground herbage production, leafy spurge stem densities, and mean weight per leafy spurge stem. The sample dates were: 5 and 19 June, 6 July, 8 August, 6 September and 8 October 1984. Three plants from each plot were dug up on 8 November to determine general condition of the roots.

Data will be collected from these plots with no retreatment for one or two additional years in order to follow the effects of chemical and mechanical treatments on leafy spurge.

No definitive conclusions can be made from these data without knowing the relative survival rate of the leafy spurge plants on each treatment one year after treatment. Several encouraging trends do show up in the data however.

Mowing leafy spurge appeared to have a little effect on the top growth. We do not know yet if this effect is significant. The total herbage production of leafy spurge and the mean weight per stem was reduced considerably. The density of live stems greatly increased for a month after the June mow treatment and then it decreased. All of the stems were dead 125 days after the June mow. The control plots had 17% of the stems still alive on the same sample date which amounted to an 87% reduction in live stems. The July mow treatment had a 98% reduction in live stems 93 days after treatment. A few of the plants on the July mow plots had mature seeds at time of treatment. The mowing treatment should be applied prior to the seed development phenophase. The July mow appeared to stimulate a small amount of additional regrowth over the control. The roots in both mowing treatments were alive but no buds were present on the first 6 inches of root except for a few buds on the roots on one plot of the July mow treatment. The roots on the control plots had numerous healthy buds on the same amount of root. If mowing has detrimental effects on leafy spurge it would probably be more effective to use two annual mowing periods rather than a single application. The first mowing should be in June before the plants start seed development and the second mowing should be of the regrowth in July just prior to peak herbage production to eliminate any possibility of flowering and seed development.

Tordon at 2 lbs ai / acre was effective in killing the top growth of the leafy spurge for the June, July and August application dates. The June treatment had 100% of the stems dead 62 days after treatment. The July treatment had 99.7% stem kill after 93 days and the August treatment had 99.1% kill of the top growth after 62 days. The roots were dead or near dead with decaying on the June and July treatments in early November. The roots on the August Tordon treatment were still alive in early November but no healthy buds were present in the first six inches.

The combination of mowing plus Tordon treatment appeared to have a little more effect on the top growth than the Tordon alone treatment. Both the June and July combination treatments had 100% of the top growth dead 62 days after treatment and no fall regrowth occurred. The roots on these plots were dead and decaying in early November in the first six inches.

Mowing of leafy spurge did have some detrimental effects. It may or may not be significant. Mowing alone may be a better alternative to no treatment in areas of leafy spurge that can be reached with a mower and cost was a factor. Tordon at 2 lbs ai / acre was effective in top growth kill. At this rate, the chemical treatment was not inexpensive and may be a major deterrent of its use. The combination of mowing plus tordon appears to be additive to some degree. Mowing may not have a cost / benefit ratio that would warrant this added expense at the 2 lbs ai / acre rate of chemical. If the rate of chemical could be reduced and still have effective kill with the addition of mowing, the total cost may be reduced.

Leafy Spurge Control by Chemical and Mechanical Treatment in 1984

Shrub Reduction by Chemical Control – 1984

Dickinson Experiment Station

Llewellyn Manske and Phillip Sjursen

Some shrub species have become problems in localized areas for ranchers and other land managers in North Dakota. The shrub stands generally occupy areas of higher than normal available soil moisture or areas with a water table within range of the roots for at least part of the growing season. Because of the available water, many areas that support dense stands of shrubs have a high potential to produce high yields in graminoid herbage if the shrub plants were reduced in size and number. Shrubs tend to increase in size and density under light grazing or no grazing pressure and decrease under heavy grazing. Houston (1961) found this to be true in Montana. This has been shown to be true in western North Dakota by Brand (1980) and in eastern North Dakota under rotation grazing systems by Manske (1980 and 1981). With increasing emphasis on land managers to use rotation grazing systems to improve range condition, the increase in shrubs on localized areas of grasslands will be a growing problem. Because of this existing problem and the potential for the problem to increase, there is a need for information on simple, economic methods for reducing shrub densities on rangeland.

Many shrub species provide cover and fall and winter food for wildlife. Some shrubs are important in late summer, fall and winter diets of livestock. Wildlife and livestock do not require nor do they generally use large and very dense stands of shrubs. A harmonious level of shrub density on rangeland that is compatible with livestock grazing and wildlife needs should be the desired goal.

A study to test the effects of chemical treatment on a few selected shrub species was started at the Dickinson Experiment Station in 1983. The trial was established on 0.50 acres located on the SW $\frac{1}{4}$, SW $\frac{1}{4}$, NW $\frac{1}{4}$ Sec. 12, T. 138 N., R. 101 W. at the Pyramid Park Experimental Area of the Dickinson Experiment Station. Each plot was 22 x 30 feet in size and arranged in a randomized block design. The chemical, Tebuthiuron (Graslan), was furnished by the Elanco products company in two concentrations, 20% and 40%, of active ingredient incorporated into dense clay pellets. Three rates, 0.25, 0.50 and 0.75 pounds of active ingredient per acre, for each concentration and a control of no herbicide were applied.

Each rate of each concentration was replicated at least twice with one rate, 0.50 lbs ai / acre and the control replicated four times. The size of the plots and the number of replications were limited by the available area of homogenous shrub densities. The herbicide was broadcast applied with a whirlybird hand spreader on 24 May 1983. No retreatment was made in 1984.

The soil was possibly Havrelon silt loam. Some additional work will be needed to confirm this preliminary soil classification. The range site was overflow. The site fits into the Sagebrush range type classification of Hanson and Whitman (1938). Silver sage (*Artemisia cana*) was the only shrub species that was included in this trial in 1983. Wolfberry (*Symphoricarpos occidentalis*) may be included at a future date.

Tebuthiuron is a herbicide designed to be effective on shrubs. The company claims that the chemical has very little effect on grass and grasslike plants at low rates. The grasses tend to increase on treated areas when the canopy cover of the shrubs is reduced. A simplified version of the theory on how the chemical works follows. The chemical is absorbed by the roots and translocated to the leaves. Photosynthesis is restricted. The leaves senesce prematurely and fall off and a new set of leaves develop. This process continues until the plant depletes its stored carbohydrates. This process may take one to four years before the plant dies completely depending on the species and the environmental conditions.

The data that were collected from these plots were: shrub density, plant height, crown diameter in two directions, north – south (N-S), and east – west (E-W) and plant species present list. Crown area and crown volume can be determined from the height and diameter measurements.

Shrub density, number of plants per unit area, was determined by counting every plant of silver sage in each plot which was 61.31 square meters. These data were converted to plants per meter square.

Each silver sagebrush plant of each plot was permanently identified by affixing a numbered tag. The individual plant height data were collected by measuring in centimeters from ground level to the apex of the tallest branch. The crown diameter data were collected by measuring the distance between the outside leaves in a north - south and an east – west direction. Two sets of height and crown diameter data were collected for each plant. One set of data included only living current years growth. The other set of data included the living portions plus the current years growth which had senesced. The difference between the two sets of data was the amount of senesced (dead) plant material. Crown area and crown volume was determined for the living portions and for the living plus dead portions of the plants. The formula used to determine crown area was:

$$c.a. = \left[\frac{D_1 + D_2}{4} \right]^2 \pi$$

The formula used to determine crown volume was:

$$c.v. = \frac{4}{3} \pi H D_1 D_2$$

A plant species present list was made for each plot. Each species was separated into four categories of relative abundance which were Dominant, Abundant, Frequent and Scarce.

A few silver sage plants that were located on or near the boundary between two plots were unintentionally placed in the wrong plot during field measurements in 1983. Since each plant had been tagged with identification numbers and measured individually, it was a simple matter to place the data with the correct plot. All of the 1983 data was recalculated and have been included in this report along with the 1984 data.

Data to detect the effects of Tebuthiuron on silver sage was collected 94 days after treatment in 1983 and 413 days after treatment in 1984. Very little effect of the Tebuthiuron at the rates and concentrations tested was detected in 1983, 94 days after treatment. Very little difference was noticed between treatments.

In 1984, the effects of Tebuthiuron on silver sage were considerably greater than in 1983. The difference in the treatment effects were also greater in 1984. Based on percentage of reduction in total plant size per treatment the sequence from most effective to least effective rate and concentration was: .75, 20%; .50, 40%; .75, 40%; .50, 20%; .25, 40%; .25, 20%; and 0.0.

These plots will be monitored for two additional years to follow the effects of Tebuthiuron on silver sage at these rates.

Hatch 1922: Short Term Grazing Systems

Dickinson Experiment Station

D. Kirby

Short duration grazing systems use: (1) multiple pastures, 3 to 60, (2) 1 to 15 day grazing periods, (3) 30 to 60 day rest periods, and (4) 1 herd stocked at a heavier rate when compared with recommended seasonlong stocking rates. It has been suggested that this system will maintain or improve range condition and increase carrying capacity over conventional rangeland management systems. This project was initiated to test his hypothesis.

The grazing trial began in June, 1981 by dividing section 16, Dickinson Experiment Station, Ranch Headquarters, into a 320 acre seasonlong (SL) pasture and 8-40 acre short duration grazed (SDG) pastures. On June 25, 1981, June 22, 1982 and June 17, 1983, 20 cow-calf pairs and 1 bull were allocated to the SL pasture and 35 cow-calf pairs and 1 bull were allocated to the SDG system. In 1984 25 cow-calf pairs were allocated to the SL pasture. Cattle were rotated every 5 days on the SDG system as pastures received 35 days rest between grazings. Drought, causing low forage production, forced removal of livestock from both systems on September 3 in 1981. In 1982, 1983, and 1984 cattle were removed October 12 and 26, and November 5 concluding 112, 131 and 131 day grazing seasons, respectively.

Forage production and utilization and livestock performance are summarized in Table 1. Forage produced and utilized was similar between grazing treatments in 1981 and 1982. In 1983 the range sites used for estimating forage production and utilization were changed to better represent the "true" sites according to the newly revised Dunn County Soil Survey. We feel the difference in forage production in 1983 on the two grazing treatments is a result of this site change and not an effect of the grazing treatment. Forage production was again greater on the SL treatment in 1984. Utilization of forage is quite similar between treatments from year to year despite the increased stocking rate on the SDG treatment. Livestock performance per head was similar but production of calf per acre was higher each year for the SDG system which reflects the increased stocking rate.

Livestock performance by year, season and 28 day weigh period are shown in Tables 2 and 3. Data from 1981 was omitted due to the shortened grazing season. Cows gained and maintained more weight over the season on the SL treatment each year. Cows on both grazing treatments began losing weight usually in the 4th weigh period which ran from mid-September to mid-October. Cows on the SDG treatment in both 1983 and 1984 were able to maintain weight better in the latter weigh periods than SL cows. Calf seasonal and daily gains were not different for the SL and SDG treatments in all years. Calf gain also dropped off dramatically in weigh period 4. This suggests some management in fall might be needed to maintain condition of cows and/or weight gain of calves.

Botanical composition (%) of cow diets on the short duration system indicated cattle select more grasses throughout the grazing season (Table 4). Grass averaged over 80% of cattle diets each year and generally increased in diets from early summer through late fall. Forbs were an important part of diets in early summer but were selected less as seasons progressed. Except for 1981, a drought year, browse contributed little to cattle diets in any season.

Research has shown that various species of grazing animals have different forage preferences. When animals don't compete for the same type of forage, an increase in stocking rate is possible without causing detrimental effects to the condition of the rangeland. Consequently, a study to determine dietary overlap of sheep and cattle on the two grazing treatments was begun in 1983.

Esophageally fistulated sheep were grazed seasonally on both short duration and seasonlong grazing treatments. Botanical composition of the collected diets were determined to class and species using microscopic analysis.

Botanical composition of sheep diets indicated that forb use was highest in early summer and summer on both grazing treatments (Tables 5-8). The last half of the grazing season showed decreases in the amount of forbs selected in diets and increases in grass and browse selection. The decrease in forb use is due to the disappearance of forb species in the latter months of the grazing season and to the decrease in palatability of forbs when mature. Forb selection on the short duration grazing treatment was higher in the early summer and summer than on the seasonlong treatment. Forb and grass use was quite similar for both treatments in the early fall and fall. Comparing sheep and cattle diets, indicates that sheep have little dietary overlap with cattle for forbs. The only competitive overlap in diets appears to be for the short, warm-season grass, blue grama (Tables 9 and 10). Any competitive overlap in diets would appear to increase in the latter part of the grazing season.
