

## **Corn In-Furrow and Sequential Fungicide Program Evaluations, Carrington; BASF Collaboration**

Justin Berg and Mike Ostlie

In 2013, a trial was conducted at the NDSU Carrington Research Extension Center in cooperation with BASF to evaluate fungicide application strategies in corn. Experimental design was a randomized complete block with four replicates. The field trial was established on a conventionally-tilled Heimdal-Emrick loam soil with 3.0 percent organic matter and 7.7 pH. Pioneer 39D97 79-day maturity corn was planted on May 23 at 29,000 plants per acre on 30-inch row spacing. In-furrow treatments were applied during planting at 5 gal/ac. V7 treatments were made on July 1 with a hand-held boom sprayer delivering 17 gal/ac through 8002 flat-fan nozzles to the center two rows of the four-row plots. The trial was combine harvested for seed yield on October 8.

An early-season vigor and stand population response to the in-furrow treatments was evident as the treated plots were statistically smaller than the untreated (Table 1). This, however, corrected itself as the growing season progressed and did not have an impact on yield. The CREC experienced below-average rainfall in 2013 thus causing nearly zero disease pressure in this dryland trial. No disease was evident throughout the entire season and there were no differences in corn stay-green measurements. There were a few minor differences in test weight and no significant differences in yield.

**Field preparation for in-furrow fungicide evaluation of corn.**

**Table 1. In-Furrow and Sequential Fungicide Programs in Corn.**

Treatment	Rate fl oz/acre	Application Timing	Population plants/ac	Emergence		Vigor		Emergence		Vigor		Test Weight lb/bu	Yield bu/ac
