

*Thirty-Fourth Annual
Western Dakota Crops Day
Research Report 2017*

34th Annual Western Dakota Crops Day

December 14, 2017

Hettinger Armory

MST

9:00 AM Registration

Coffee and doughnuts. Free time to view exhibits and visit with Program Sponsors.

10:00 Early Bird Drawing and Opening Announcements

10:10 Crop Variety Updates and Highlights of Ongoing Regional Crop Production Research

Dr. Caleb Dalley, Weed Scientist, NDSU Hettinger Research Extension Center.

Ryan Buetow, Extension Agronomist, NDSU Dickinson Research Extension Center.

Dr. Chris Graham, Extension Agronomist, SDSU West River Ag Center, Rapid City.

Patrick Wagner, SDSU Extension Entomology Field Specialist, Rapid City

12:00 Lunch

Provided by Program Sponsors. Free time to visit with sponsors.

1:00 Crop Variety Updates and Highlights of Ongoing Crop Production Research (cont.)

John Rickertsen, Research Agronomist, NDSU Hettinger Research Extension Center.

1:30 Farm Management Program Overview & Crop Profitability

Levi Helmuth, Farm Management Education, Bismarck State College

2:00 Are Those Cows On Your Cropland?

Jay Fuhrer, Soil Health Specialist, Natural Resources Conservation Service.

2:45 Conclusion

Drawing for door prizes, coffee and opportunity to visit with sponsors.

Acknowledgments

The Hettinger Research Extension Center gratefully acknowledges and thanks the following companies and organizations for their financial support and participation in this year's Western Dakota Crops Day. Those listed below have provided for the noon meal and have made this event possible. We greatly appreciate their commitment and support.

2017 Western Dakota Crops Day Sponsors

Hettinger Area Chamber of Commerce
AGT Foods
BASF
Farm Credit Services of Mandan Gartner
Seed Farm
Helena Chemical Company
Legacy Seeds
North Dakota Grain Growers
Association Proseed
Pulse USA
South Dakota Wheat Growers Southwest
Grain
Stone Mill LLC
United Grain Corporation

We also acknowledge and thank the following individuals for their willingness to cooperate with us at off-station plot sites and in providing us with materials for this publication. Their participation has enabled us to compile the enclosed information which would not otherwise be possible.

Glenn Martin, Dickinson Research Extension Center
Ryan Buetow, Dickinson Research Extension Center
Dr. Chris Graham and Bruce Swan, SDSU West River Ag Center, Rapid City
Dr. Joel Ransom, NDSU, Fargo
Neal and Justin Freitag, Scranton
August and Perry Kirschmann, Regent
Dan Christman, Hettinger
USDA – ARS Northern Great Plains Research Center, Mandan
Keith Gietzen, Glen Ullin
Pat Doll, Hannover

This work is supported by the USDA National Institute of Food and Agriculture, Hatch projects ND06278 & ND06280.

Interpreting Statistical Analysis

Field research involves the testing of one or more variables such as crop varieties, fertilizer rates, weed control methods, planting dates, etc. Field testing of such variables is conducted in order to determine which variety, fertilizer rate, herbicide, date, etc. is best for the particular area of production. The main objectives of crop production research are to determine the best means of producing a crop and how to maximize yield and economic return from farming.

Agricultural researchers use statistics as a tool to help differentiate production variables so meaningful conclusions can be drawn from the data gathered from research trials. Attempts are made to control human error and environmental conditions such as soil variability by replicating the variable in question. For example, there were four plots (replications) of the every variety grown in the Hettinger HRSW variety trial. These plots are randomly placed throughout the trial to help eliminate differences that might be a result of soil or other variations.

The coefficient of variation (C.V.%) listed at the bottom of each data column is a relative measure of the amount of variation recorded for a particular trait expressed as a percentage of the mean for that trait. It is a measure of the precision or effectiveness of the trial and the procedures used in conducting it. The numbers that you see in the tables are an average of all four replications. The C.V. for yield in the 2017 Hettinger HRSW variety trial was 11.1% meaning that there was a 11.1 percent average variation between high and low yields among replications. In summation, a trial with a C.V. of 6% is more precise and reliable than a trial with a C.V. of 18%. When comparing yields, trials with a C.V. less than 15% are generally considered reliable.

To determine if one variety, fertilizer rate, herbicide, planting date, etc. is better than another, use the least significant difference (LSD 5%) value at the bottom of each data column. The LSD 5% value is a statistical method of indicating if a trait like yield differs when comparing two hybrids. If the yield of hybrid A exceeds hybrid B by more than the LSD value, you can conclude that under like environmental conditions, hybrid A is expected to significantly out-yield hybrid B. The LSD value allows you to separate variety yields or any other variable and determine whether or not they are actually different.

For example, in the HRSW trial, the variety HRS 3419 averaged 41.2 bu/ac in 2017 compared to LCS Breakaway at 34.8 bu/ac. Did the yield difference between these varieties differ significantly? Compare the yield difference of 6.4 bu/ac between the varieties ($41.2 - 34.8$) to the LSD 5% value of 5.7 bu/ac. Since the 6.4 bu/ac difference is more than the LSD value of 5.7 bu/a, the varieties do differ significantly in yield. If the difference between these two varieties would have been 3.5 bu/ac, their difference would have been less than 5.7 bu/ac; therefore, the yield difference between these varieties would not have been significant.

When selecting a variety or hybrid evaluate as much performance information as possible. Give more weight to information from trials close to home and look at relative performance over many locations and years. Performance averaged over many tests is called “yield stability.” Good yield stability means that, while a variety may or may not be the best yielder at all locations, it ranks high in yielding potential at many locations and years. A hybrid that ranks in the upper 20% at all locations exhibits better yield stability than one that is the top variety at one location but ranks in the lower 40% at the other locations.

¹ Small grains GDD, is growing degree days calculated with 95°F as the maximum temperature and 32°F as the base temperature.

² Corn GDD, is growing degree days calculated with 86°F as the maximum temperature and 50°F as the base temperature.

Trials Not Published

The following trials were not published in this report because of very poor yields and significant plot variation due to the drought. Trial average yields are reported below.

Trial	Average Yield
Hettinger Roundup Ready Canola VT	300 lb/ac
Hettinger Clearfield Canola VT	273 lb/ac
Hettinger SU Canola VT	60 lb/ac
Hettinger Flax VT	3.6 bu/ac
Hettinger Lentil VT	355 lb/ac
Hettinger Clearfield Lentil VT	339 lb/ac
Hettinger Chickpea VT	460 lb/ac
Hettinger Safflower	Not harvested, very poor stands from wireworms.

¹Disease reaction scores from 1-9, with 1 = resistant and 9 = very susceptible, NA = not available.

²A.Can. = Agriculture and Agri-Food Canada; ARS = USDA Agricultural Research Service; CDC = Crop Development Centre, University of Saskatchewan; MT = Montana State University; NE = University of Nebraska; ND = North Dakota State University; SD = South Dakota State University; WB = WestBred. **Bold** varieties are those recently released, so data are limited and rating values may change.

³Days to heading relative to Jerry.

⁴Straw strength = 1 to 9 scale, with 1 strongest and 9 weakest. These ratings may change as additional data become available.

⁵Based on the average of several environments, and should be used for comparing varieties. The environment can impact the height of varieties.

⁶Relative winter hardiness rating: 1 = excellent, 10 = very poor. These values are subject to change as additional information becomes available.

Table 2. Analytical milling and baking characteristics of selected varieties evaluated across five localities (Hettinger, Langdon, Minot, Prosper and Williston) in 2016.

¹Refers to agent or developer: Can. = Agriculture Canada, WB = Westbred, ND = North Dakota State University.

²Straw Strength = 1-9 scale, with 1 the strongest and 9 the weakest. Based on recent data. These values may change as more data become available.

³Days to Heading = the number of days from planting to head emergence from the boot. Averaged from several locations in 2017.

⁴Disease reaction scores from 1-9, with 1 = resistant and 9 = very susceptible. NA = Not adequately tested. Foliar Disease = reaction to tan spot and septoria leaf spot complex.

⁵Alzada has a disease-resistance package that makes it more adapted to drier growing conditions (for example, western North Dakota).

⁶Indicates yields and/or quality often have been higher than would be expected based on visual symptoms.

⁷Low cadmium accumulating variety.

Table 2. Durum wheat variety quality descriptions, milling and processing data averaged for five years (2011-2016) from drill strips (32 locations/year).

Average	61.2	89	51	452	13.5	74	8.8	4.2	

¹Wheat protein is reported on a 12 percent moisture basis.

²Gluten index is unitless. Numbers less than 15 = very weak and greater than 80 = very strong gluten proteins.

³Pasta Color Score: Higher number indicates better color, with 8.5+ typically considered good.

⁴Overall Quality is determined based on agronomic, milling and spaghetti processing performance.

⁵Average of 27 drill strips instead of 32 for other varieties in Table 1. Grenora average of four locations instead of five for other varieties in Table 3.

⁶Alzada has good quality when grown in environments where it is adapted. Low test weight can affect quality in some environments.

⁷Low cadmium accumulating variety.

¹ M = malting; MT = being tested in plant-scale tests for malting and brewing quality; F = feed; SP = special uses (hull-less).

² BARI = Busch Agricultural Resources Inc.; MN = University of Minnesota; MT = Montana State University; ND = North Dakota State University.

³ R = rough; S = smooth; H = hull-less.

⁴ S = short; L = long.

⁵ R = resistant; MR = moderately resistant; MS = moderately susceptible; S = susceptible; NA = not available.

⁶ Moderately resistant to Fusarium head blight.

⁷ Lower DON accumulations than other varieties tested.

⁸ Recommended as a malting barley in western U.S.

Weed Control Trials in 2017
Caleb Dalley, HREC, Hettinger, ND, 2017

During the 2017 growing season, weed control trials were established in spring wheat, durum, barley, oats, canola, field pea, lentils, chickpea, faba bean, flax, and safflower, as well as several trials that were conducted postharvest. Unfortunately, due to the lack of rainfall, most of these trials offered limited amounts of useful information. During the months of May and June, there was less than one inch of total rainfall. Many of the trials were conducted to evaluate the potential use of preemergence applied herbicides for weed control in the previously mentioned crops. Lack of rainfall resulted in poor incorporation and activation of these herbicides and in no case did any of the tested herbicide treatments result in herbicide injury to the crops in which they were applied. Most preemergence herbicides require a minimum of a half-inch of rainfall to adequately incorporate and activate the herbicide. This activation is best when this rainfall comes as a single event, rather than accumulation of lesser amounts of rainfall spread over several days or weeks. Lack of rainfall also limited weed emergence and growth, limiting the amount of data that could be collected from trials evaluating postemergence applied herbicides. With the extreme drought conditions, most crop yields in trials were extremely low and variable. However, due to July and August rainfalls, that encouraged weed growth in fields that had already been harvested, several trials were conducted to evaluate post-harvest weed control. Trials being reported this year include a trial evaluating preemergence and early postemergence herbicides that have potential utility in oats, and evaluation of fall and spring applied herbicides for downy brome control prior to planting field peas, and the evaluation of herbicides that can be used to control kochia and Russian thistle post-harvest.

Postharvest Control of Kochia and Russian Thistle

Caleb Dalley, HREC, Hettinger, ND, 2017

Three field trials were conducted to evaluate herbicide options for controlling kochia following harvest. During 2017, drought conditions led to many small grain fields to be harvested for forage rather than grain. Following forage harvest kochia, Russian thistle and other weeds populations rapidly flourished in the absence of any crop cover. Herbicide options were explored in an effort to control these weeds. Three trials were conducted near Hettinger North Dakota. Two trials were located on fields that had been planted to barley and harvested for hay forage, the other had been planted to cereal rye and had been grazed. All three fields had high populations of kochia, although one of the fields was primarily infested with Russian thistle. Results at all three location differed considerably.

Location previously planted to rye. Herbicide treatments were applied on August 18, 2017 to kochia that ranged from 2 to 18 inches in height with an average height of 4 inches. Weeds present at this site were kochia, redroot pigweed, common lambsquarter, and common mallow. At 7 DAT, all treatments containing Gramoxone control kochia 97 to 99%, regardless of addition of adjuvant or 2,4-D. The next best treatment was Sharpen which provided 81% control. These are both quick acting contact types of herbicides. Glyphosate alone controlled kochia 77% at 7 DAT and improved to 80% or more at later evaluations. The addition of dicamba (Sterling Blue) and 2,4-D or Starane Ultra did not significantly improve control. Starane Ultra alone controlled kochia 68 to 77%. The addition of 2,4-D or dicamba improved control. Other treatments provided fair control of kochia, and reduced continued growth.

Table 1. Kochia control in field planted to cereal rye and grazed.

Abbreviations: DAT, days after treatment; AMS, ammonium sulfate; MSO, methylated soybean oil; HSOC, high surfactant oil concentrate; NIS, non-ionic surfactant.

Location previously planted to barley. Herbicide treatments were applied on July 26, 2017 to kochia ranging from 2 to 12 inches averaging 6 inches. This location was primarily infested with kochia and volunteer barley. The best treatment at all evaluation dates was Gramoxone, which controlled kochia 92% at 14 DAT. Glyphosate alone, even at 48 oz/A provided poor control of kochia. The only other treatments providing good kochia control were Distinct (dicamba + diflufenzoxypr) or WideMatch (clopyralid + fluroxypyr). This field will need to be monitored for possible resistance to glyphosate.

Russian thistle location. Herbicide treatments were applied on August 22, 2017. Weeds present at this location included Russian thistle, kochia, common lambsquarters, and green foxtail. The primary weed, Russian thistle was 12 to 18 inches in height, which was greater than an ideal height. Other weeds were not as tall, but were above ideal heights for good control. At 7 DAT, as with the other locations, Gramoxone, with and without adjuvants or 2,4-D provided the greatest control of kochia, Russian thistle and common lambsquarters. Glyphosate alone or tank-mixed with dicamba and 2,4-D or Starane Ultra or Sharpen or Distinct provided excellent control of kochia, Russian thistle and common lambsquarters at 14 DAT and thereafter. Other treatments provide only fair or poor control of these three weeds. Weeds were above ideal height and it was encouraging that control was still possible with both glyphosate and Gramoxone tank-mixes.

Fall and Spring Application of Dual and Broadaxe for Downy Brome Control in Spring Field Peas

Caleb Dalley, HREC, Hettinger, ND, 2017

Fall POST treatments were applied on October 28, 2016 to a fallow field heavily infested with downy brome. These fall treatments were evaluated for downy brome control 13 days after treatment and again in the spring on May 2, 2017 before planting (186 DAT). At 13 DAT, glyphosate tank-mixed with Dual II Magnum (metolachlor) or Broadaxe XC (sulfentrazone + metolachlor) controlled downy brome 89 to 94%, compared to 80 to 82% with glyphosate alone. When evaluated in the spring before planting, downy brome control was 95 to 99% with glyphosate tank-mixed with Dual II Magnum or Broadaxe, compared to 64 to 66% with glyphosate alone. Field pea were planted and then spring POST treatments were applied on May 5, 2017. Downy brome control was evaluated 21 and 28 DAT (spring POST). At 28 DAT, fall POST tank-mixes of glyphosate with Dual II Magnum or Broadaxe continued to provide 92 to 100% control of downy brome, compared to 48% control for glyphosate alone in the fall. Spring POST tank mixes of glyphosate with Dual II Magnum or Broadaxe controlled downy brome 93 to 97% compared to 86% for a spring only glyphosate application or 90% for a fall and spring application of glyphosate. Extremely dry conditions occurred at Hettinger in 2017. Less than an inch of rainfall occurred during the months of May and June. Due to the dry conditions, pea germination and survival was very low. Stand counts were taken on June 9. Plots treated with fall POST tank-mixes had stand counts of 34 to 38 peas plants per square meter compared to 12 to 25 plants per square meter for spring POST treatments. The desired stand counts was 75 to 80 plants per square meter. Pea height was measured on June 21. Pea heights ranged from 20 to 23 cm for fall POST tank-mixes compared to 17 to 22 for spring POST treatments. Dry conditions persisted for the remainder of the cropping season and did not allow for harvesting the peas due to low population and low seed set. However, it was very apparent that fall POST allowed for better establishment of field pea, even when control of downy brome was similar for fall and spring treatments. It was also apparent that fall application of metolachlor provided much better control than glyphosate alone.

Granular Ammonium Sulfate (AMS) was added to all treatments at a rate of 8.5 lbs/100 gallons spray solution.

Herbicide Options for Weed Control in Oats

Caleb Dalley, HREC, Hettinger, ND, 2017

A field trial was conducted to evaluated herbicides with potential utility for weed control in oats. None of the herbicides tested in this trial are registered for use in oats at this time. Oats 'High Test' were planted on May 12, 2017 at a rate of 80 lbs/A and a depth of 2 inches using a 10-ft John Deere 1590 no-till drill with 7.5 inch row spacing. Starter fertilizer (18-46-0) was applied at 40 lbs/A at planting. Prior to planting, urea fertilizer (46-0-0) was applied at a rate of 40 lbs/A, and the field was treated with glyphosate (Cornerstone Plus @ 24 oz/A + AMS) on April 29 to control existing weeds. PRE treatments were applied on May 12 using a tractor mounted research sprayer at a spray volume of 10 gal/A. Oats emerged on May 21. EPOST application of Armezon + COC (Trt 12) was applied on May 23 when oats were at the 1-feaf stage. POST application of Armezon + COC (Trt 13) was applied on June 13 when oats were at the 4-leaf stage measuring 10.5 inches to the longest extended leaf. Oats were evaluated for injury at 3, 4, and 6 weeks after emergence. At 4 WAE, the only treatment resulting in injury was the application of Armezon at the 4-leaf stage. At the 6 WAE evaluation, injury was also observed when Armezon was applied at both the 1-leaf (8%) and 4-leaf (28%) stages. None of the other herbicide treatments resulted in visual injury. However, Hettinger was extremely dry in 2017 and daily rainfall never exceeded 0.25 inches in either May or June. This limited incorporation and activation of PRE herbicides which may have had different results in a year with average precipitation. Oat height was measured at 7 weeks after planting. No differences in oat height were observed. Oats were harvested on August 17. No differences in yield were observed. Yields were very low, ranging from 4 to 10 bu/A, and were highly variable due to the extreme drought conditions. Further evaluations are needed under more ideal growing conditions in order to come to a conclusion on the safety of these herbicides.

Nitrogen Relationships in Soybean in Southwest North Dakota

Best management practices are needed to achieve optimal crop yields. Soybean has the ability to form a symbiotic relationship with nitrogen (N)-fixing bacteria; however, it may be possible to increase yield through addition of synthetic N fertilizer, however addition of N reduces the plants need to form a relationship with N-fixing bacteria. It may be possible that with a dryer environment in southwest North Dakota that the N-fixing bacteria are less productive. The Dickinson Research Extension Center worked with the Hettinger Research Extension Center to observe the effects of different agronomic management strategies on soybean growth and yield. Objectives of the research were to evaluate yield and growth differences between four N management strategies applied to two soybean cultivars with different maturities grown at two populations. The research was conducted at two locations, however only data from the Hettinger location was recorded due to herbicide damage. Soybean production has been increasing in southwest North Dakota recently and there are many questions on the proper management for the regional differences compared to the Red River Valley. 2017 was a difficult year with drought conditions, however rains during August contributed to soybean yields (Tables 1 and 2).

Table 1. NDAWN rainfall data for Hettinger, ND during the 2017 growing season.

Month	Precipitation (in)
April	1.18
May	0.60
June	0.34
July	1.68
August	1.78
September	1.89
October	0.01

Rainfall in August aligned with reproductive growth of soybeans allowing the plants to attain decent average yields considering the poor conditions during vegetative growth. Although there were no significant differences among N treatments alone (Table 2.), there were differences in yield with the interaction between populations of 80,000 and 160,000 plants per acre and the N treatments (Table 3.), this interaction needs to be further investigated before making any conclusions. No significant yield differences were found between populations, 80,000 plants/acre averaged 23.3 bu/ac while 160,000 plants/acre averaged 24.2 bu/ac. This lack of difference in yield may be due to the drought, however more work will need to be conducted to observe the effects of plant population on yield in western ND.

In August, five soybean plants per plot were excavated to observe the number of nodules per plant. Table 2 shows that there were significant differences between the inoculated and non inoculated treatments. While there is no significant decrease in nodule production with the fertilized treatment, a higher rate of N would most likely further decrease nodule number. While there is a difference in number of nodules, this did not translate into a difference in yield.

Table 2. Nodules per plant and yield across nitrogen treatments for soybean in Hettinger, ND 2017.

Nitrogen Management	Nodule/plant	Bushels/acre
No inoculant/no N added	0.6b	22.4
No inoculant/30 lbs N added	1.4b	24.1
Inoculant/no N added	23.3a	23.9
Inoculant/30 lbs N added	19.9a	24.4
LSD (0.05)	10.44	ns

Table 3. 2017 soybean yields in Hettinger, ND across plants per acre and nitrogen treatments. Soybeans were planted May 18th.

Nitrogen Management	Yield	
	bu/acre	
	80,000	160,000
No inoculant/no N added	24.0ab	20.9b
No inoculant/30 lbs N added	21.3b	26.8a
Inoculant/no N added	23.4ab	24.5ab
Inoculant/30 lbs N added	24.4ab	24.5ab
LSD (0.05)	3.9	

Drought conditions in 2017 reduced yield capacity for soybeans. Under drought conditions a plant population half of the recommended seeding rate was able to yield just as well as the full rate. While it may be possible that with higher rainfall a larger yield is possible, more work should be conducted before changing recommendations. Under drought conditions with a reduced yield potential, it could be possible to reduce seed input costs without losing bushels.

Hettinger Soybean Planting Date Study

John Rickertsen, HREC, Hettinger, ND, 2017

Soybean acreage has increased over the years in North Dakota (ND) but mostly in the East. A recent realization that there is limited data on soybean production research in Western ND, amidst growing interest from farmers and stakeholders to start or expand production in Western, Central, and Northern, ND, has highlighted research needs to focus as well on areas often considered, marginally productive. Soybean is a profitable crop, useful in diversifying rotations and for use in later planting when wet conditions have not permitted timely small grain planting. Two critical decisions that farmers make each year that greatly affect yield potential and economic returns are, when to plant, and variety selection (maturity class). It is important to assess the performance of soybean maturity classes and planting west of the Missouri River, as the climate and soils are very different than the tradition soybean growing regions in eastern North Dakota. The objectives are therefore to facilitate the farmer's planting decisions, by assessing the performance of three soybean maturity classes in response to three planting dates and three plant populations across locations. Growth stages, and yields will be assessed for three varieties, three planting populations, across three planting dates in Hettinger, (Adams County), and Minot (Ward County, and Carrington (Foster County).

Three soybean varieties of three maturity classes were be planted in 2015, 2016 and 2017 at Hettinger (dryland), Minot (dryland), and Carrington (dryland and irrigated) to assess growth performance and grain yields. For Hettinger the planting dates were May 4, May 19 and June 2. In 2017, three planting densities of 200,000, 175000, and 150,000 plants/ac were evaluated for each variety. Data was recorded on flowering, height, maturity date, yield, test weight, seed protein and seed oil content.

The results in the following tables shown May19 to have the highest yields followed my May 4 then June 2. In 2015 and 2016 planting date had no impact on test weight, oil or protein. In 2017 test weights and protein increased and oil decreased with later planting dates. Seeding rates had no effect on yields. From the results so far, our recommendations is to plant soybean the second to third week of May for best yields and to allow soybeans to mature before fall freeze.

Soybean Planting Date - 2017	Hettinger, ND

C.V. %	0.1	--	7.8	2.4	2.6	1.5	22.3

*May 19 date had very poor stands from pheasant damage right after planting, which reduced yields for that date.

Subsituted yields for variety 30-20 from nearby soybean yield trial planted on May 19.

Soybean Planting Date Three Year Averages - 2015 - 2017	Hettinger, ND
--	----------------------

Treatment	Mature Date	Harvest Date	Plant Height	Test Weight	Seed Oil	Seed Protein	Grain Yield
Planting Date							
May 4	9/5	9/16	24.7	52.5	17.4	33.0	27.0
May 19*	9/14	9/22	24.3	53.2	17.2	33.3	31.0
June 2	9/19	9/27	24.3	52.8	17.0	33.6	26.3

* Used vareity 30-20 yield (26.3 bu/ac) from nearby soybean yield trial in 2017.

2017 National Sunflower Survey in Southwest North Dakota

In the fall of 2017 the National Sunflower Survey was conducted across North Dakota (ND), South Dakota, Minnesota, Colorado, Kansas, Nebraska, and Texas in the U.S. and also in Manitoba. The survey observes yield limiting factors such as weeds, insect damage, and diseases along with yield potential factors such as plant population, head size, and kernel size. Southwest ND faced extreme drought conditions in 2017.

32 fields were surveyed in southwest ND. With each field surveyed, a number 1 and number 2 yield limiting factor were identified (Table 1.). Drought was the number 1 factor in 59% of fields surveyed. Plant spacing within the row was highest occurring factor as the second most limiting factor. This was likely from poor emergence after planting due to the drought.

Table 1. Frequency of occurrence as number 1 and number 2 yield limiting factors in sunflower for 32 fields in southwest North Dakota in 2017.

Factor	Yield Limiting Factor #1	Yield Limiting Factor #2
		%
No problem	0	22
Birds	6	0
Disease	0	0
Drought	59	13
Uneven plant growth	0	9
Hail	3	9
Herbicide damage	0	0
Insects	0	0
Lodging	0	0
Plant spacing within the row	19	28
Weeds	13	13
Other	0	6

The drought conditions in 2017 were a major factor in sunflower production. It had an effect on crop growth directly and indirectly including reduced herbicide activity, reduced disease incidence, and reduced lodging along with issues with emergence. The top 5 weeds found throughout the southwest in order of occurrence were kochia, green foxtail, Russian thistle, volunteer grains, and Canada thistle. The disease with the highest presence for the region was Phoma. Rainfall across the region was highly variable, and as so yields surveyed for the region ranged from 875 to 3,844 lbs/acre with an average of 1,663 lbs/acre.

For more information on the survey or for statewide and national results contact Ryan Buetow at ryan.buetow@ndsu.edu.
