North Dakota Canola

Variety Trial Results for 2018 and Selection Guide

Hans Kandel and Adnan Akyüz (NDSU Main Station); Mike Ostlie, Blaine Schatz and Kelly Bjerke (Carrington Research Extension Center); Eric Eriksmoen, Joe Effertz and Austin Kraklau (North Central Research Extension Center, Minot); Bryan Hanson, Travis Hakanson and Lawrence Henry (Langdon Research Extension Center); and Jerry Bergman, Gautam Pradhan, Justin Jacobs and Tyler Tjelde (Williston Research Extension Center)

Canola is a major oil crop in the northern Great Plains, particularly in North Dakota. In 2018, North Dakota accounted for approximately 80 percent of the 1.99 million canola acres planted in the U.S. This publication summarizes canola hybrid performance at the various North Dakota State University Research Extension Centers. The relative performance of the hybrids is presented in table form.

Give special attention to yield results of those trials nearest to your production area when evaluating varieties or hybrids in these trials. Also, attempt to view yield averages of several years rather than using only one year's data as a determining factor. In addition, consider other agronomic characteristics, such as maturity, lodging score and oil percentages, if available.

Research specialists and technicians helped with the field work and data compilation. The assistance given by many secretaries in entering data in respective portions of the document is very much appreciated. A special thank you goes to Lisa Johnson, Extension Plant Sciences secretary, for assisting in the compilation of this publication.

2018 Growing Season Update

Canola fieldwork began by the beginning of May. Planting progress was delayed, and by May 14, 23 percent of the acres had been planted, compared with the average of 34 percent on the same date. On May 14, the topsoil moisture was rated at 36 percent short and 47 percent adequate.

Early canola stands varied across the region, depending on soil moisture availability and rainfall after planting. By July 9, 91 percent of the canola crop was flowering, compared with the average of 74 percent on the same day. Many parts of the state experienced warm midsummer conditions. By the last week in July 2018, the North Dakota office of the National Agricultural Statistics Service reported the canola crop condition as 73 percent "good" and 6 percent "excellent," compared with 32 "good" and 1 percent "excellent" in 2017.

By Sept. 17, 86 percent of the canola acres were harvested, which was slightly ahead of the 82 percent average on the same date. In general, the 2018 season was favorable and yield is estimated to be 1,920 pounds per acre for North Dakota.

¹Statewide values are calculated based on all available locations in North Dakota rather than the mathematical average of the list above.

About This Publication

Variety trial data from all NDSU Research Extension Centers for all crops can be found at www.ag.ndsu.edu/varietytrials. The agronomic data presented in this publication are from replicated research plots using experimental designs that enable the use of statistical analysis. The LSD (least significant difference) numbers beneath the columns in tables are derived from the statistical analyses and only apply to the numbers in the column in which they appear.

If the difference between two varieties exceeds the LSD value, it means that with 95 or 90 percent probability (0.05 or 0.10 level), the higher-yielding variety has a significant yield advantage. If the difference between two varieties is less than the LSD value, then the variety yields are considered similar. The abbreviation NS is used to indicate "no significant difference" for that trait among any of the varieties.

The CV is a measure of variability in the trial. The CV stands for coefficient of variation and is expressed as a percentage. Large CVs mean a large amount of variation that could not be attributed to differences in the varieties. In the tables, the mean indicates the average of the observations in the column. Only compare values within the table and look for trends for the desired trait among different experimental sites and years.

Oil and harvest yield were adjusted to 8.5 percent moisture. Oil content is intended to differentiate between hybrids at one location, LSD values should be used to determine differences between hybrids.

The oil content data are not intended to be compared between locations. Tables 4 and 5 are summary tables, with yields expressed as a percentage of the trial mean (indicated on the bottom) of the various trials reported in subsequent tables.

Presentation of data for the varieties tested does not imply approval or endorsement by the authors or agencies conducting the tests. NDSU approves the reproduction of any table in this publication only if no portion is deleted, appropriate footnotes are given, the order of the data is not rearranged and NDSU is credited for the data.

¹LL = Liberty Link, SU = Sulfonylurea, CL = Clearfield System, RR = Roundup Ready, TR = Traditional Oil Type, HO = High Oleic Oil Type.

²Lodging: 0 = none, 9 = lying flat on the ground.

³Cover - visual rating of percent area of plot covered by plant growth. This is a measure of stand and vigor. Plants were at 5- to 6-leaf stage.

⁴DAP = Days after planting.

⁵Roundup Ready checks in the trial.

Table 10. 2018 Canola - Liberty Link and Clearfield - Minot - Authors, E. Eriksmoen, J. Effertz and A. Kraklau.

Company/ Brand	Hybrid	Days to	Flower	Days to	Plant	Oil Content (%)	Seed Yield	
		Flower (DAP) ¹	Duration (days)	Maturity (DAP)	Height (inch)		2018	3-yr. Avg. -----(lb/a)-----
