*Released Thursday, January 31, 2013*

*Mark Svoboda, National Drought Mitigation Center*
Presentation overview

• Topics to be covered:
  – Crop water requirements
  – Soil water holding capacity
  – Rooting depth
  – Water balance calculations
How much water does a crop need?

- Alfalfa = 22 – 24 inches
- Sunflower = 18 - 21 inches
- Corn = 19 – 20 inches
- Soybean = 16-17 inches
- Spring wheat = 12 - 16 inches
- Barley = 11 – 16 inches
Cumulative water-use by ET, HRSW, 1979-1987 Mandan

Irrigated + Adequate N: $Y = 0.106X^2 - 0.00243X^3 + 0.27$
Irrigated + Deficient N: $Y = 0.110X^2 - 0.00244X^3 + 0.27$
Fallow: $Y = 0.0914X^2 - 0.00253X^3 + 0.03$

Bauer, Black, Frank, 1989
Water use and drought

- Metabolism
- Structure
- Transpiration
  - Moves nutrients from the roots
  - Regulated by stomatal opening
    - Cooling of plant
    - Movement of water through the plant
    - Movement of CO$_2$ into the leaves
    - Water use correlates to yield
    - Challenges are to maximize available water for transpiration and maximize efficiency of water use
Soil water availability in 2013

- Carryover from the end of the 2012 growing season
  - Soil type
  - Crop type:
    - rooting depth
    - water requirement
    - productivity of the crop
- Recharge during the fall and winter
- Rainfall during the growing season
- Rooting depth of crop
Total rainfall for the period = 7.9 inches

Safe to assume that soil was depleted to the rooting depth of the crop grown (16” needed minus 8” rainfall, 8 removed from the soil or all that it could hold)
Soil water holding basics

Saturation: All pores are full of water. Gravitational water is lost.

Field Capacity: Available water for plant growth.

Wilting Point: No more water is available to plants.

Rooting depth and crop water use characteristics
Rooting Characteristics

Unrestricted effective rooting depths of selected mature crops.

Lundstrom, 1988
Fig. C. Maximum and median depths of root length growth measured with minirhizotron technology in Phase I Alternate Crops Experiment, 1995-1997. Median depth is that at which half of root length growth is above, half below.

Source: Crop sequence calculator
Crop characteristics with regards to soil water use

Length of active growing season is the best overall guide to the relative amount of soil water depletion. Rooting depth is also an indicator of depletion.

Merrill, Tanka, Krupinsky, Liebig and Hanson, 2007
How deep will an inch of moisture move during recharge

• Depends on the moisture status of the soil
  – One inch rain that fully infiltrates into the soil moves:
    – Fine sand: 12 inches
    – Loam: 6 inches
    – Clay: 8 inches

• Heavy rain events usually mean surface runoff

• Frozen soils in the spring will not allow infiltration
Water Balance Diagram

Evapotranspiration

Soil moisture utilization

Precipitation

Recharge

Runoff

ET > Precip = Soil moisture utilization

Precip > ET = Recharge, surplus, and runoff

NDSU
Some practical numbers

- A full profile shortly after planting 2012 (2 inches per foot of soil available water)
- Depleted root zone by harvest
  - Spring wheat 8 inches (down to four feet)
  - Corn 10 inches (down to five feet)
- Fall/winter recharge (1.2 inches) (top 8 inches at field capacity)
- Roots grow to water, but can’t grow through a dry zone and are impeded by compaction.
- We need additional 6.8 (following wheat) and 8.8 inches (following corn) to fill the profile
Wheat Yield vs. Starting Soil Water

5.3 bu/a/in

Seed Yield (bu/a) vs. Available Water (in)
Corn Yield vs. Starting Soil Water

Seed Yield (bu/a) vs. Available Water (in)
Corn Yield vs Precipitation, CO
(15 July – 25 August)

bu/a = 33.9 + 7.49 * in
$r^2 = 0.70$
Corn Yield vs Precipitation Western ND (15 July – 25 August)

\[ \text{bu/acre} = 9.9x + 34.1 \]
\[ R^2 = 0.36 \]
Practices to increase water availability

• Tillage
  - Minimize or eliminate tillage

• Residue management
  - Snow catch is good
  - Reduced surface evaporation
  - Excessive residue can delay emergence and increase frost risks in the spring
A couple of suggestions for 2013

- Growing deeper rooting and high water requiring crops after barley, spring wheat, or soybeans may provide ~>2 inch of moisture
  - Avoid corn after corn or after sunflower!

- Small grains will be less risky than corn or soybeans in soils with little or no stored moisture
  - If winter recharge is good and early spring rains refill the profile, a good crop would be likely
  - Corn and soybeans will need July and August rains regardless of spring recharge.
